Citation: Wu B, Liu C, Potter D, Cui D (2019) Taxonomic reconsideration of *Prunus veitchii* (Rosaceae). *PhytoKeys* 115: 59–71. <https://doi.org/10.3897/phytokeys.115.29219>

Abstract

Prunus veitchii was published in 1912 and was treated as a synonym of *P. serrulata* var. *pubescens*. The information about this taxon is relatively scarce. When consulting specimens of *Prunus* L., type materials of *Prunus veitchii* were found to belong to three taxa and *P. veitchii*, *P. concinna*, *P. japonica* var. *zhejiangensis*, *C. jingningensis* and *C. xueluoensis* were found to be conspecific. The taxonomic status of *P. veitchii* is reconsidered in the present paper. Morphometric analyses were performed to evaluate the significance of differences between *P. veitchii* and *P. serrulata* var. *pubescens*. The results show that the leaves of *P. veitchii* are significantly smaller and narrower than the leaves of *P. serrulata* var. *pubescens* and the peduncle and pedicels are shorter. According to the results of morphometric analyses, *P. veitchii* should be treated as a separate species. To address these results, a lectotype of *P. veitchii* is designated here and *P. concinna*, *Cerasus jingningensis* and *C. xueluoensis* are here designated as synonyms of *P. veitchii*.

Keywords

Prunus, *Prunus serrulata* var. *pubescens*, typification, synonyms, China

Introduction

Cerasus A. Gray, the taxon that includes species commonly known as cherries, is a group that is famous for germplasm resources of edible fruits and flowering trees and shrubs. Historically, *Cerasus* has been treated either as a subgenus of *Prunus* L. or as a separate genus (Wen et al. 2008). In the past twenty years, molecular phylogenetic analyses (Bortiri et al. 2001; Lee and Wen 2001; Wen et al. 2008; Shi et al. 2013; Chin et al. 2014) have supported recognition of *Prunus sensu lato*, including *Cerasus*,

as a single genus and have also shown that, with the removal of the species in sect. *Microcerasus*, a monophyletic *Cerasus* can be recognised. Although the inclusion of *Cerasus* within *Prunus* is no longer as controversial as it used to be, there are still many problems with the taxonomy of this clade (Wu et al. 2018).

Prunus veitchii Koehne (Koehne 1912) is a species of shrub cherry that occurs at altitudes above 1000 m in western Hubei Province, China. It was treated as a synonym of *P. serrulata* var. *pubescens* Wilson by Wilson (1916), a treatment followed by “Flora Reipublicae Popularis Sinicae” (Yü and Li 1986) and “Flora of China” (Li and Bartholomew 2003) and also by Koehne (1917), albeit with reservation. We found that the type materials of *P. veitchii* actually belonged to three taxa and that the voucher of Wilson’s treatment is not the same plant as the specimen on which Koehne’s description was based. This means that the taxonomic status of *P. veitchii* needs to be redefined.

Meanwhile, we also found that *P. veitchii*, *P. concinna*, *P. japonica* var. *zhejiangensis*, *Cerasus jingningensis* and *C. xueluoensis* should all be conspecific due to their similarities in morphology and habitat. The histories of all of these taxa are relevant and are described below.

First, along with the publication of *P. veitchii*, Koehne (1912) described another shrub cherry, *P. concinna*, from a similar habitat. Due to the lack of materials, Koehne was uncertain about its status and the name is still unresolved today. Second, Chang (1992) described *P. japonica* var. *zhejiangensis* based on Zhang Fanggang & Li Zhiyun 5309, which was collected from southern Zhejiang Province. This variety (Figure 1) was thought to be different from the typical variety in its persistent ovate stipules and black fruit (Chang 1992). However, it is strange that Chang did not include this variety in “Flora of Zhejiang” (Editorial Board 1993), which was published in the following year and for which Chang was involved in compiling most of the content for Rosaceae, including *Prunus* L. Although the taxon was later included in “Flora of China” (Li and Bartholomew 2003), it was overlooked in later publications (Wang 2014, Yan et al. 2017). Third, Xu et al. (2012) described a new species of cherry, *C. jingningensis* (Fig. 1), based on specimens collected from southern Zhejiang Province. Recently, *P. japonica* var. *zhejiangensis* was treated as a synonym of *C. jingningensis* by Liu et al. (2017). Finally, *C. xueluoensis* was published by Nan et al. (2013) based on Cheng-Hui Nan 040301, which was collected from western Hubei Province.

Here, we use morphometric analyses to test the distinct nature of *P. veitchii* and *P. serrulata* var. *pubescens* and conclude that the former should be recognised as a separate species. We designate a lectotype for *P. veitchii* and reduce *P. concinna*, *Cerasus jingningensis* and *C. xueluoensis* to its synonymy.

Materials and methods

Herbarium specimens from A, AU, CSFI, DAV, E, GH, HBG, HHBG, HX, IBK, IBSC, IFP, JJF, JXU, K, KUN, LBG, MO, NAS, NE, NY, PE, UC, US, ZJFC and

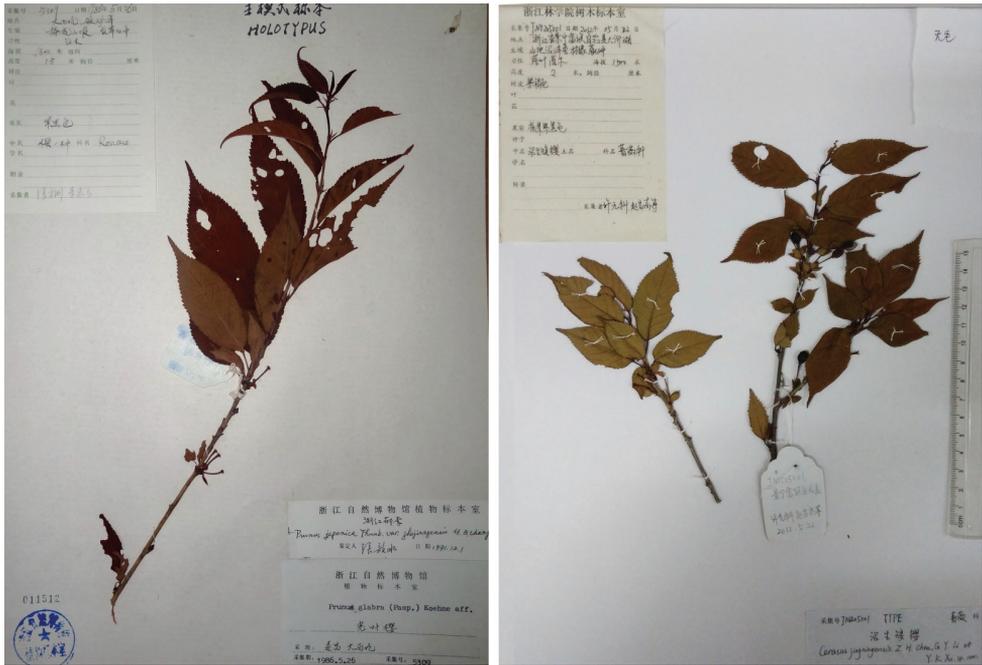

Figure 1. Holotypes of *Prunus japonica* var. *zhejiangensis* (left, photograph by Fanggang Zhang) and *Cerasus jingningensis* (right).

ZM (Chinese Academy of Sciences 2018, Thiers, [continuously updated].) were examined by visiting the herbaria or through the Chinese Virtual Herbarium (Chinese Academy of Sciences 2018) and Global Plant database (JSTOR 2018). To evaluate the differences between *P. veitchii* and *P. serrulata* var. *pubescens*, specimens from different origins were selected to gather morphological data and which were subjected to morphometric analyses. Seven floral characters and eight leaf characters (Table 1) were selected for analyses, following Chang et al. (2007), though some characters used by Chang et al. (2007) were discarded because it was not possible to collect enough relevant data from the available specimens. A total of 26 specimens for floral characters and 44 specimens for vegetative characters were measured (see Appendix 1). Measurements were made manually with rulers for borrowed specimens or performed using Digimizer version 4.6.0 (MedCalc Software 2018) for online images.

A non-parametric Kruskal-Wallis ANOVA was conducted to evaluate the significance of the difference in measured characters between *P. veitchii* and *P. serrulata* var. *pubescens* in each character, as not all characters follow a normal distribution. Box plots were created to illustrate the differences. Data analyses were performed in R version 3.5.1 (R Core Team 2011) and diagrams were created by using ggplot2 package (Wickham 2016).

Table 1. Floral characters and vegetative characters used in morphometric analyses.

Code	Floral Character	Code	Vegetative Characters
A	Peduncle length (cm)	H	Petiole length (cm)
B	Pedicel length (cm)	I	Leaf length (cm)
C	Length of calyx tube (cm)	J	Leaf width (cm)
D	Diameter of calyx tube top (cm)	K	Angle of leaf base (°)
E	Length of calyx lobe (cm)	L	Angle of leaf apex (°)
F	Width of calyx lobe (cm)	M	Length of leaf apex (cm)
G	Ratio of length and width of calyx lobe	N	Ratio of leaf length and petiole length
		O	Ratio of length and width of leaf

Results

After examining the type specimens, other collections, relevant literature and plants in the field, we determined that *P. veitchii*, *P. concinna*, *P. japonica* var. *zhejiangensis*, *C. jingningensis* and *C. xueluoensis* must be conspecific. Their original descriptions are not essentially different (Table 2). Although the type specimens of these taxa cannot all be compared directly because they were collected in different seasons and stages of development, it was clear that they are conspecific after consulting specimens collected from the type localities in different seasons.

The result of basic statistics and Kruskal-Wallis ANOVA are summarised in Table 3. The box plots (Figure 2) show that there is no significant overlap between *P. veitchii* and *P. serrulata* var. *pubescens* for most of the measured characters. Moreover, ANOVA showed that the means of almost all measured characters differ significantly, except width of the calyx lobes.

Discussion

Prunus veitchii was treated as a synonym of *P. serrulata* var. *pubescens* by Wilson, a treatment that was followed by Koehne with reservation (Koehne 1917). Koehne (1917) mentioned that the sepals of *P. veitchii* are ovate and shorter and the leaflets are smaller than those of *P. serrulata* var. *pubescens*. Consistent with Koehne's observation, our morphometric analyses show that the leaves of *P. veitchii* are smaller, while the sepals are shorter and wider. The leaves of *P. veitchii* are also obviously narrower than the leaves of *P. serrulata* var. *pubescens*, while the calyx tubes are longer and the peduncles and pedicels are shorter. These results indicate that *P. veitchii* should not be treated as a synonym of *P. serrulata* var. *pubescens*.

The short peduncle was thought to be an important feature that distinguished *P. sargentii* Rehder from members of the *P. serrulata* complex (Chang et al. 2007). According to the key to classify the *P. serrulata* complex and its related species published by Chang et al. (2007), *P. veitchii* is similar to *P. sargentii*, having an umbellate or subumbellate inflorescence, sessile or short-pedunculate, consisting of 1–4 flowers

Table 2. Characteristic description of *Prunus veitchii*, *P. concinna*, *P. japonica* var. *zhejiangensis*, *Cerasus jingningensis* and *C. xueluoensis*, from the original literature (the description of *P. concinna* contains Koehne's description (Koehne 1912) in the original literature and Rehder's description (Rehder 1940) is based on the individuals introduced in Harvard Arnold Arboretum).

	<i>P. veitchii</i>	<i>P. concinna</i>	<i>P. japonica</i> var. <i>zhejiangensis</i>	<i>C. jingningensis</i>	<i>C. xueluoensis</i>
Life Form	Shrub	Shrub	Shrub	Shrub	Shrub, small tree
Lamina	–	narrow-elliptic to oblong-ovate, oblong-obovate	–	ovate, ovate-elliptic, obovate-elliptic	elliptic, obovate-elliptic
Leaf Length	–	3–6 (8) cm	–	3–6 cm	3–7 cm
Leaf Width	–	–	–	1.5–3 cm	1.5–3 cm
Leaf Margin	Incisively serrate	Sharply and rather finely serrate, doubly serrate	–	Acuminately serrate, biserrate	Serrate, biserrate
Leaf Apex	–	–	–	Acuminate, cuspidate	Acuminate, caudate
Leaf Base	–	Cuneate, rounded	–	Cuneate, rounded	Subrounded to broadly cuneate
Petiole	–	3–8 mm	–	4–10 mm	5–9 mm
Inflorescence	Umbellate, 1–3 flowered	Umbellate (Koehne, 1912), 1–4 flowered (Rehder, 1940), 1–2 flowered (Koehne, 1912)	–	Umbellate, subumbellate, 1–3 flowered	Umbellate, 2–4 flowered
Peduncle	No	No	–	Very short or no peduncle	Inconspicuous
Bract	Leaf like	–	–	Leaf like, subovate, ovate-oblong	Obovate, spatulate, fan-shaped, lobate
Pedicel	0.8–1.3 cm	0.8–1.5 cm (Rehder 1940), 0.8–0.9 cm (Koehne 1912)	–	0.8–1.8 cm	0.6–2.5 cm
Calyx Tube	Tubular with acute base, obconical, 8–10 mm long	Tubular (Rehder, 1940), obconically-tubular (Koehne, 1912), 9 mm long	–	Tubular-campanulate	Narrow tubular, apical enlarged, 6–10 mm long
Sepal	Ovate, oblong, entire	Ovate to ovate-oblong (Rehder 1940), ovate-triangular (Koehne 1912), entire	–	Ovate-triangular, entire	Ovate-triangular, entire
Published year	1912	1912	1992	2012	2013

with tubular hypanthia, triangular-lanceolate sepals with entire margins and white to reddish petals. Nonetheless, *P. veitchii* is definitely different from *P. sargentii*, which has small and elliptic or obovate-elliptic shaped leaves and short petioles, as opposed to the leaves of *P. sargentii* are elliptic-obovate or oblong-obovate and the length of leaves and petioles can reach 12 cm and 3 cm long (Rehder 1940). In addition, the distribution of *P. veitchii* is significantly different from that of *P. sargentii*. The former is mainly distributed around central and eastern China, while the latter is mainly distributed in northern Japan, the Korean peninsula and far eastern Russia (Chang et al. 2007). Therefore, we think that it is better treated as an separate species, based on current evidence.

E. H. Wilson 66 (Veitch Expedition) collected in April 1900, was cited as the voucher when Koehne described *P. veitchii*. However, this collection number is a source of some confusion. Number “66” was re-used by Wilson for a specimen collected in 1907 during his expedition for Arnold Arboretum, which was determined by Koehne (1912) as a certain form of *P. triflora*. Another number “66a”, also collected in April 1900, was cited as *P. tenuiflora* by Koehne in “*Plantae Wilsonianae*” (Koehne 1912). There are 7 sheets (Table 4) designated as Wilson 66, collected in April 1900, in the Global Plant database (JSTOR 2018), three of which are not congruent with the original description. Amongst these three specimens, one of them, A00241703, contains Wilson’s handwriting, which says ‘*Prunus serrulata* var. *pubescens*’, indicating it is the voucher for Wilson’s treatment of *P. veitchii* as a synonym of *P. serrulata* var. *pubescens*. It is reasonable to infer that the mixed collection led Wilson to propose a taxonomic treatment, different from Koehne.

As for why this species was published again several times, we believe that there are several reasons besides the confusing voucher. First, the vouchers of this species are deposited in different herbaria in different countries, so it would have been dif-

difficult to consult all of them in the past. Second, few sources, especially those easily accessible to Chinese plant taxonomists, record this species. *P. veitchii* is not included in “Flora Hubeiensis” (Fu 2002) and it is listed as one of the synonyms of *P. serrulata* var. *pubescens* in “Flora Reipublicae Popularis Sinicae” (Yü and Li 1986) and “Flora of China” (Li and Bartholomew 2003), which makes it easy to be ignored. And neither “Flora Hubeiensis” (Fu 2002) nor “Reipublicae Popularis Sinicae” (Yü and Li 1986) record *P. concinna*, which is only listed as a species that could not be treated in “Flora of China” (Li and Bartholomew 2003) because the authors had not seen the type specimens. Third, this species sometimes has three winter buds growing side by side, which has led some authors to treat it mistakenly as a member of section *Microcerasus* (Nan et al. 2013, Wang 2014, Liu et al. 2017). However, this trait is quite unstable. From observations of herbarium specimens and plants in the field, we found that the number of buds varies from one to three or four and mostly only one bud can be found (Figure 3).

According to the International Code of Nomenclature (ICN) (McNeill et al. 2012), it is necessary to designate a lectotype of *P. veitchii*, since the voucher points to more than one taxon. We choose the barcoded sheet US00130697 as the lectotype, since a label with Koehne’s handwriting, ‘*Prunus veitchii* Koehne’ is affixed to it.

Table 4. Type and original materials of *Prunus veitchii*, *P. concinna*, *P. japonica* var. *zhejiangensis*, *Cerasus jingningensis* and *C. xueluoensis*.

Specimen	Type	Collecting locality	Identification

Prunus japonica Thunb. var. *zhejiangensis* Y. B. Chang, Bull. Bot. Res. 12(3): 271–274, 1992. Type: China, Zhejiang, Suichang, Daixikeng, Tieluyang, 26 May 1986, F. G. Zhang & Z. Y. Li 5309 (holotype: ZM!).

Cerasus jingningensis Z. H. Chen, G.Y. Li & Y. K. Xu, Jour. of Zhejiang For. Sci. & Tech. 32(4): 81–83, 2012, syn. nov. Type: China, Zhejiang, Jingning She Autonomous County, Dayanghu, 22 May 2012, Y. K. Xu, C. G. Zhao et al. JN1205001 (holotype: ZJFC!).

Cerasus xueluoensis C. H. Nan & X. R. Wang, Ann. Bot. Fennici 50: 79–82, 2013, syn. nov. Type: China, Hubei, Enshi Tujia and Miao Autonomous Prefecture, Xuanen County, Xueluozhai, 3 April 2009 C. H. Nan 040301 (holotype: NF!).

Description. Small trees, sometimes shrubs, deciduous, up to 3 m tall. Winter buds ovoid, apex acute, 1–3(4). Stipules lanceolate, sometimes ovate and lobed. Leaves elliptic to obovate-elliptic, 3–8 × 1.5–3.5 cm, apex acuminate, base subrounded to broadly

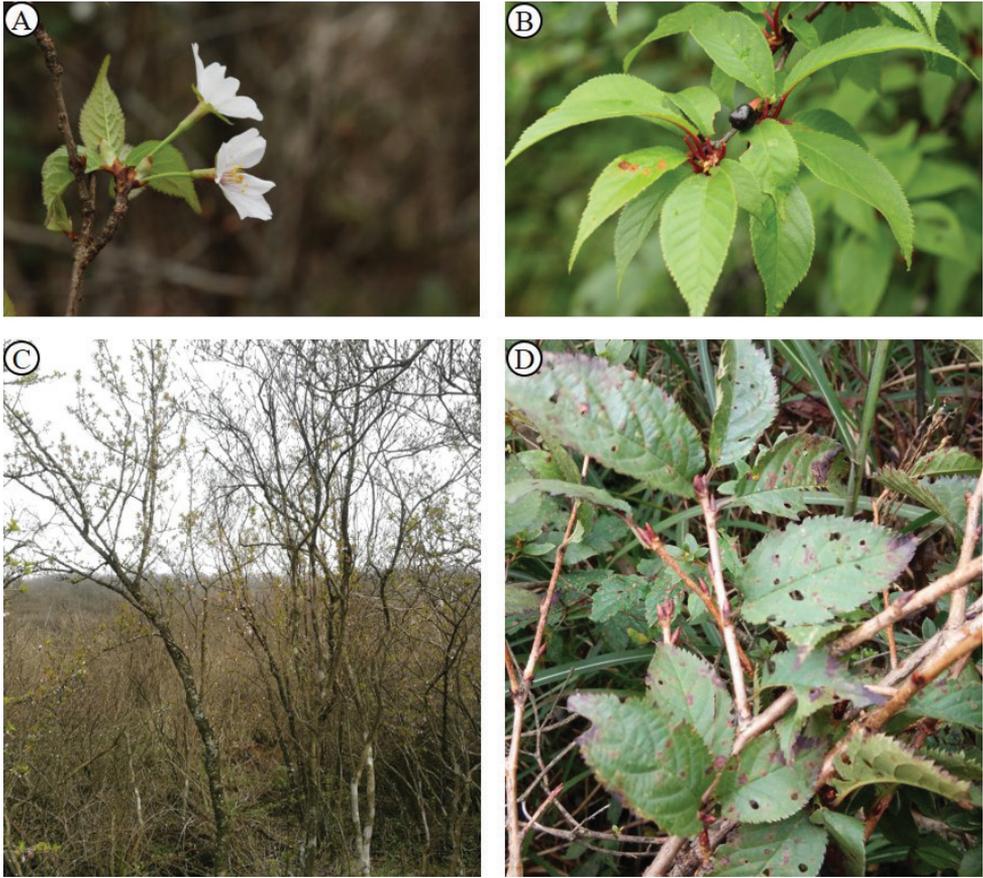

Figure 3. *P. veitchii*. A. Flower branch. B. Fruit Branch. C. Individual. D. Variation of the winter buds.

cuneate, abaxially pale green and glabrous, sparsely pilose or sometimes pilose when young, adaxially green and glabrous or sparsely pubescent, margin serrate or biserrate. Petiole 4–10 mm, glabrous or sparsely pilose, apex with 2 nectaries or not. Inflorescence umbellate or sometimes corymbose, peduncle short or inconspicuous, 1–4-flowered, involucre bracts spatulate or obovate-elliptic, bracts ovate, obovate or spatulate, margin serrate. Pedicel 6–25 mm, glabrous or sparsely pilose. Hypanthium tubular, 6–10 × 1.5–3 mm, reddish-green to purplish, glabrous or sparsely pubescent. Sepals ovate-triangular to triangular-lanceolate, 3–5 mm, margin entire. Petals white or pinkish, obovate, apex emarginate, ca. 10 mm long. Stamens ca. 30–40. Style glabrous. Drupe ovoid or globose, ca. 8–10 mm in diam., glabrous, black when ripe. Flowering March–April, fruiting May–June.

Distribution and habitat. Anhui, Fujian, Hubei, Hunan, Jiangxi, Zhejiang Provinces, usually occurs in mountain-top thickets at elevations of 800 to 1700 m (Figure 4).
