Abstract

Based on morphological and phylogenetic evidence, a new genus of Melastomataceae (Melastomateae), *Nothodissotis* Veranso-Libalah & G.Kadereit, **gen. nov.**, is described from Atlantic Central Africa. *Nothodissotis* is distinguished from other African Melastomateae genera by its calyx-lobes that are notched at apex and asymmetrical (vs. entire and symmetrical). *Nothodissotis* includes two species: the type species *N. barteri* (Hook.f.) Veranso-Libalah & G.Kadereit, **comb. nov.** (syn. *Dissotis barteri* Hook.f.), and the new species *N. alenensis* Veranso-Libalah & O. Lachenaud, **sp. nov.**, described and illustrated here. Both species are restricted to open vegetation on rock outcrops within the forested region of Atlantic Central Africa. *Nothodissotis barteri* has a scattered distribution in Cameroon, Equatorial Guinea, Gabon and Príncipe Island, while *N. alenensis* is endemic to the Monte Alén massif in Equatorial Guinea, an area where *N. barteri* does not occur. *Nothodissotis alenensis* differs from *N. barteri* by its hypanthium bearing sessile appendages with penicillate hairs (vs. stalked stellate appendages) and its staminal appendages that are much smaller in antepetalous than in antesepalous stamens (vs. subequal in all stamens). The conservation status of both *N. barteri* and *N. alenensis* is assessed as Vulnerable in accordance with IUCN criteria.

Introduction

Melastomataceae are a large pantropical family with about 4700 species in 170 genera (Clausing and Renner 2001). The majority of their species (c. 3000) occur in the Neotropics, with an important secondary centre of diversity in tropical Asia (c. 1000 species). Continental Africa is relatively poor with c. 330 species, while Madagascar has about the same number (Renner 1993). Most African representatives of the family belong to the pantropical tribe Melastomateae (excluding Marcetia DC. and allies now treated in Marcetieae), which includes about 650 species in 32 genera (Michelangeli et al. 2013; Veranso-Libalah et al. 2017a; Rocha et al. 2018). In continental Africa, around 186 species in 13 genera of Melastomateae are currently recognised (Veranso-Libalah et al. 2017a, b). Dissotis Benth. has long been regarded as the largest African genus of the tribe, with about 120 species on the continent (Renner 1993) and a single species in Madagascar (Jacques-Félix 1995). Its delimitation, however, has been problematic (Fernandes and Fernandes 1969; Jacques-Félix 1981, 1995), and phylogenetic study has shown the genus to be polyphyletic (Veranso-Libalah et al. 2017a). As a result, the genera Dissotidendron (A.Fern. & R.Fern.) Veranso-Libalah & G. Kadereit, with 11 species, and Dupineta Raf., with five species, both previously regarded as subgenera of Dissotis, have been segregated from the latter. The rest of the Dissotis species form a clade together with Antherotoma Naudin, Chaetolepis gentianoides (Naudin) Jacq.-Fél. (formerly treated in Nerophila Naudin) and African species of Osbeckia L. (sensu Jacques-Félix 1995), and are paraphyletic with respect to these three genera; the phylogenetic relationships and revised taxonomy of this group (hereafter referred to as 'Dissotis and allies') are the subject of a forthcoming paper (Veranso-Libalah et al. in prep.).

The affinities of the little-known Central African species *Dissotis barteri* Hook.f. were not investigated by Veranso-Libalah et al. (2017a). However, this species was included in a later phylogenetic and biogeographical study of the group (Veranso-Libalah et al. 2018) using three plastid (*accD-psaI*, *ndhF* and *psbK-psbL*) and two nuclear markers (nrETS and nrITS). In that study, *D. barteri*, together with an undescribed species from Equatorial Guinea, were recovered in a monophyletic clade separate from *Dissotis* and allies (see Fig. 1). Jacques-Félix (1981, 1983a) had previously treated *D. barteri* in *D.* sect. *Macrocarpae* A.Fern. & R.Fern., but this is not supported by its morphology or by our molecular phylogenetic results (Veranso-Libalah et al. 2018). Both *D. barteri* and the new species from Equatorial Guinea differ from the members of *D. sect. Macrocarpae* (and indeed from the rest of the genus) by being deciduous (vs. evergreen) shrubs, and by their calyx lobes that are notched at apex and asymmetrical (vs. entire and symmetrical). Therefore, both molecular and morphological evidence support their exclusion from *Dissotis*.

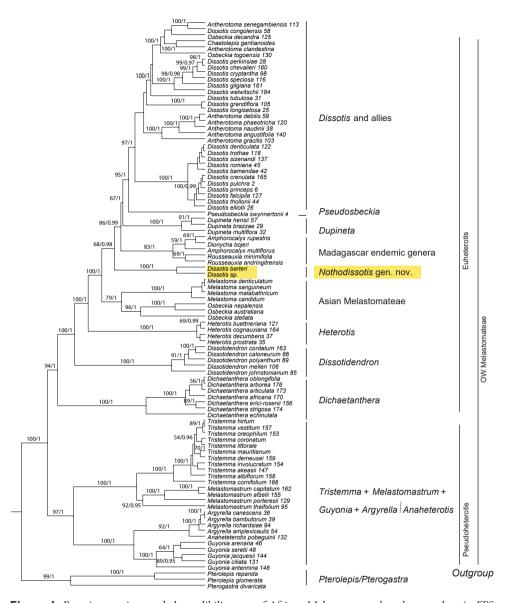

Figure 1. Bayesian maximum clade credibility tree of African Melastomateae based on nuclear (nrITS and nrETS) and plastid (accD-psaI, ndhF and psbK-psbL) matrices. Values above branches refer to bootstrap values resulting from the ML analysis (only values \geq 50) and posterior probabilities resulting from Bayesian inference (only values \geq 0,95). Modified from Veranso-Libalah et al. (2018).

The above-mentioned new species was previously misidentified as *Dissotis thollonii* Cogn., and was cited under this name in Parmentier and Geerinck's (2003) checklist of Equatorial Guinean Melastomataceae. These authors reported 16 genera and 57 species of Melastomataceae from Equatorial Guinea, including five *Dissotis* species: *D. barteri*,

D. congolensis (Cogn.) Jacq.-Fél., D. hensii Cogn. [\equiv Dupineta hensii (Cogn.) Veranso-Libalah & G.Kadereit], D. multiflora (Sm.) Triana [\equiv Dupineta multiflora (Sm.) Raf.] and D. thollonii. While the first four species were correctly identified, D. thollonii does not occur in Equatorial Guinea, and most of the specimens cited under this name in the checklist (Parmentier & Esono 1530, 2721, 2763 and 3453) actually represent our new species. As discussed above, this species is very close to D. barteri, being a ramose shrub with stems and leaves bearing simple hairs, inflorescences few-flowered, and calyx-lobes asymmetrical, while D. thollonii is an unbranched shrub with hairs of the vegetative parts more or less branched, inflorescences many-flowered, and calyx-lobes symmetrical. Parmentier and Geerinck (2003) cited two other specimens under D. thollonii, Lejoly 99/004 and 99/345, of which the former has not been traced (it is apparently not in BRLU), while the latter is sterile and cannot be identified, but differs from the other four collections in vegetative characters.

In this paper we describe a new genus of African Melastomateae, *Nothodissotis* Veranso-Libalah & G.Kadereit, to accommodate both *Dissotis barteri* and the new species from Equatorial Guinea discussed above. The former species becomes *Nothodissotis barteri* (Hook.f.) Veranso-Libalah & G.Kadereit, while the latter is described as *N. alenensis* Veranso-Libalah & O.Lachenaud. A review of relevant literature (Keay 1954; Fernandes and Fernandes 1969, 1978; Wickens 1975; Jacques-Félix 1983a, 1983b) confirms that *N. alenensis* differs from all taxa of African Melastomateae so far described.

Material from the following herbaria was consulted for this paper: BR, BRLU, C, EA, K, MO, P, UPS and WAG (Thiers 2018). The description of the new species is based on herbarium specimens and data derived from field notes; all measurements (except plant height) thus refer to dry or rehydrated material were made for both species, following the IUCN criteria (IUCN 2012). The extent of occurrence (EOO) and area of occupancy (AOO) were estimated using GeoCAT (Bachman et al. 2011) with a cell width of 2 km. A distribution map is provided for both species of *Nothodissotis*, as well as a key to the species of the genus, and a key to the currently recognized genera of African Melastomateae.

Taxonomic treatment

Nothodissotis Veranso-Libalah & G.Kadereit, gen. nov. urn:lsid:ipni.org:names:60478296-2

Type. Nothodissotis barteri (≡ Dissotis barteri Hook. f.)

Morphological diagnosis. *Nothodissotis* species resemble *Dissotis* by their 5-merous flowers, calyx with caducous lobes and tube not accrescent on the fruit, presence of intersepalar appendages, dimorphic stamens with the connective bearing bipartite ventral appendages and a well-developed pedoconnective, anthers opening by an introrse apical pore, and cochleate seeds. They differ by being deciduous shrubs (vs. evergreen

Digital microscope photographs of the hypanthia of *Nothodissotis* spp. (**A–D**) and SEM photographs of the seeds of *N. barteri* (**E–H**). **A, B** hypanthium of *Nothodissotis alenensis* (*Parmentier & Esono 3453*); cl = calyx-lobes and ia = intersepalar appendages **C, D** hypanthium of *N. barteri* (*Ngok Banak 1196*) **E, F** seeds of *N. barteri* in dorsal view **G, H** same in lateral view (*Parmentier 3544*).

shrubs and herbs) and having the calyx-lobes notched at apex and asymmetrical (vs. entire and symmetrical); the latter character is unique within African Melastomateae.

Description. Deciduous, ramose shrubs, 1.5–4 m tall; stems 4-angular to cylindrical, glabrous or strigillose; internodes short, nodes setulose or strigillose (Figs 2, 3). Leaves elliptic with appressed hairs on both sides; 3–5-nerved from the base, margins entire or minutely serrulate. Inflorescences terminal, with 1-7(-15) flowers, flowers 5-merous, pedicellate, subtended by a pair of caducous short ovate bracts. Hypanthium broadly urceolate, with scattered appendages, these either sessile and penicillate (N. alenensis; Fig. 2) or stipitate and bearing a stellate crown of hairs at their apex (*N. barteri*; Figs 2, 3). Intersepalar appendages present, similar to hypanthial appendages but much larger, and caducous (Fig. 2 A–D). Calyx-lobes contorted in aestivation and completely concealing the floral buds, elliptic to obovate, asymmetrically notched and bearing penicillate hairs at apex, uniformly pubescent outside, caducous. Petals mauve, broadly obovate, glabrous except for the ciliate margin. Stamens 10, dimorphic in size but not in colour, pedoconnective well-developed, connective with bipartite ventral appendage, anther falcate, opening by an introrse apical pore. Ovary with a crown of persistent bristles, style simple, linear, glabrous. Fruits capsular, enclosed within the hypanthium, splitting loculicidally in 5 valves, the seeds attached on placentas borne on a central column. Seeds (only known in *N. barteri*; see Fig. 2 E–H) cochleate, exarillate, with parallel rows of tubercles.

Etymology. Derived from the Greek word 'nothos' meaning false, and *Dissotis*, the genus which *Nothodissotis* most closely resembles.

Distribution and habitat. *Nothodissotis* includes two species in Atlantic Central Africa, both of which are restricted to rocky outcrops within the equatorial rainforest zone (Fig. 4).

Distribution and habitat. *Nothodissotis barteri* is sparsely distributed in Cameroon (Ebo forest), south-eastern Equatorial Guinea (near Nsork), northern Gabon, and Príncipe Island (Fig. 4). It occurs exclusively on rock outcrops at 370–1000 m elevation, mainly in low shrubby vegetation near the edge of the rocks ("manteau arbustif") where it is locally dominant, and sometimes also as isolated plants in rocky grassland dominated by *Afrotrilepis pilosa* (Boeck.) J.Raynal (Cyperaceae).

Phenology. Flowering recorded mainly from November–February, once in August; fruits in March, May–June, August, October and December.

Conservation status. Vulnerable [VU B2ab(iii)]. The EOO of *Nothodissotis barteri* is estimated to be 82,625 km² (above the upper limit for Vulnerable status under sub-criterion B1) and its AOO to be 48 km² (within the limit for Endangered under sub-criterion B2). The species is sparsely distributed in Cameroon, Equatorial Guinea, northern Gabon and Príncipe island, and is restricted to rocky outcrops where it occurs in low shrubby vegetation or grassland. It is known from 21 collections representing eleven subpopulations, most of which (except three on Príncipe island) lie outside protected areas. In most of its range, bushfires and agriculture (mostly pineapple plantations) represent the main threats to its habitat; planned tourism development in Príncipe is another threat. A decline in habitat extent and quality is therefore expected. The eleven subpopulations represent a total of ten locations (sensu IUCN 2012), fall-

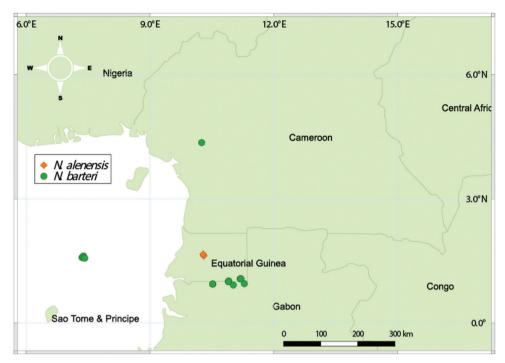

Figure 4. Distribution of Nothodissotis species.

ing within the limit for Vulnerable status, and the species is therefore assessed as Vulnerable under these conditions B2ab(iii).

Notes. This species, originally described from Príncipe Island (Hooker 1871), has since been reported from Gabon (Jacques-Félix 1983b) and Equatorial Guinea (Parmentier and Geerinck 2003). The collections cited above from Cameroon are the first for the country and represent an important range extension northwards.

The seeds of this species have not been described previously (e.g. Jacques-Félix 1983b). They are cochleate, c. 0.5×0.35 mm, and bear rounded tubercles arranged in parallel rows (Fig. 2 E–H).

Two specimens, probably from the same field collection by Barter in 1859, are housed in K, with neither of them designated as the holo- or isotype. For this reason, we designate the specimen K000313101 as the lectotype and K000313102 as the isolectotype.

Nothodissotis alenensis Veranso-Libalah & O. Lachenaud, sp. nov. urn:lsid:ipni.org:names:60478297-2 Figs 2A, B; 5

Type. EQUATORIAL GUINEA. Río Muni: Monte Alén National Park, Engong rock slab, 5 km west of Engong village, 1°37'N, 10°18'E, 1100 m, 11 May 2002 (fl & buds), *Parmentier & Esono 2763* (holotype: BRLU! [BRLU0000194]; isotype: BRLU! [BRLU0000197]).

Diagnosis. This new species differs from N. barteri by its hypanthial appendages that are sessile with penicillate hairs (not stipitate with a crown of stellate hairs) and its more strongly dimorphic stamens, the staminal appendages being much longer in antesepalous stamens than in antepetalous ones (vs. staminal appendages \pm equal in length in all stamens).

Description. Deciduous shrub, 1.5–2.5 m tall; stems glabrous except for strigillose pubescence at the nodes; internodes short, 15-80 mm long (Fig. 5A). Leaves simple, opposite, petiole 8-17 mm long with appressed pubescence; blades elliptic, 50-95 × 15-30 mm, base obtuse, apex acute, margins minutely serrulate, hairs appressed on both sides, longitudinal nerves 3(5) from the base, somewhat prominent adaxially, strongly so abaxially and with simple appressed pubescence (Fig. 5B, C). Inflorescence terminal, 1–4 flowered, the flowers 5-merous; pedicels 2–3.5 mm long with strigillose pubescence (Fig. 5D). Bracts 1 pair per flower, at the base of the hypanthium, pubescent outside, 5-8 × 2-5 mm, caducous. Hypanthium broadly campanulate, 8.5-10 mm long, 7-8.5 mm in diameter in fully opened flowers, with scattered sessile appendages bearing simple penicillate hairs, arranged radially and increasing in size from bottom to top. Intersepalar appendages present, elliptic, c. 2 mm long, with short appressed pubescence and a tuft of long hairs at the apex, caducous. Calyx-lobes uniformly pubescent outside, glabrous inside, asymmetrically obovate and notched at apex, 10–15 × 5–8 mm, contorted in aestivation and completely concealing the floral buds, caducous. Petals 26-30 × 30-40 mm, mauve, broadly obovate, glabrous except for the ciliate margin. Stamens 10, dimorphic in size; antesepalous stamens 5, filament 8–12 mm long, pedoconnective 15–18 mm long, curved, ventral appendage bipartite 4–6 mm long, anther falcate, 10–14 mm long; antepetalous stamens 5, filament 7–10 mm long, pedoconnective 3.5-4.5 mm long, ventral appendage bipartite, ca. 1 mm long, anther falcate, 8–13 mm long (Fig. 5E). Ovary with a crown of persistent bristles, style 25–30 mm long, red, glabrous; stigma simple. Fruit and seeds not seen.

Additional specimens examined. EQUATORIAL GUINEA. Río Muni: Monte Alén National Park, Monte Alén 2 rock slab, 1°40'N, 10°17'E, 1125 m, 12 Feb 2001 (ster.), *Parmentier & Esono 1530* (BRLU0000197!); Monte Alén National Park, Engong rock slab, 5 km west of Engong village, 1°37'N, 10°18'E, 1100 m, 10 May 2002, (fl. buds), *Parmentier & Esono 2721* (BRLU0000195!); Monte Alén National Park, Monte Alén 2 rock slab, 1°40'N, 10°17'E, 1110 m, 27 May 2002 (fl.), *Parmentier & Esono 3453* (BRLU0000196!).

Etymology. The species is named *alenensis* after Monte Alén range and national park in Equatorial Guinea, where it is apparently endemic.

Distribution and habitat. *Nothodissotis alenensis* is endemic to Monte Alén National Park in Equatorial Guinea (Rio Muni), where it occurs in low shrubby vegetation on rocky outcrops ("manteau arbustif") at \pm 1100 m a.s.l. (Fig. 4).

Phenology. Flowering in May.

Conservation status. Vulnerable [VU D2]. *Nothodissotis alenensis* is endemic to Monte Alén National Park in Equatorial Guinea, where it has been collected four times and is known from two rock outcrops, representing two subpopulations. Its EOO can-

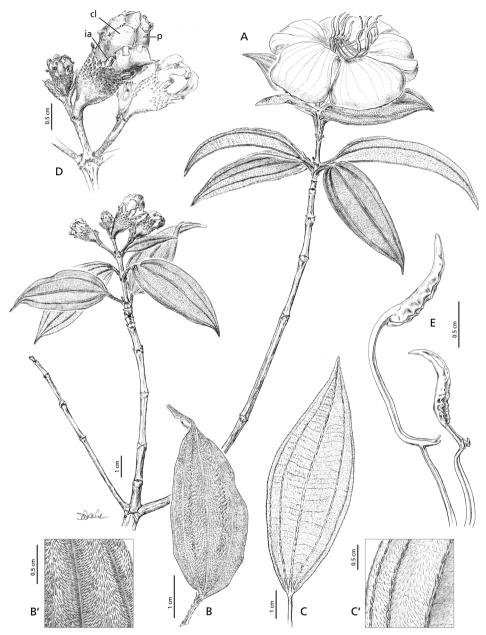

Figure 5. *Nothodissotis alenensis*, **A** habit **B, B**' leaf adaxial surface **C, C**' leaf abaxial surface **D** floral buds in different developmental stages; cl = calyx-lobes, ia = intersepalar appendages, p = petals **E** stamens of the outer (left) and inner (right) stamen whorls (drawn from *Parmentier & Esono 1560, 2721, 2763* and *3453*). Illustration by Doris Franke.

not be calculated (since only two sites are known) while its AOO is estimated to be 8 km², within the limit for Critically Endangered status under criterion B2. The species occurs in a remote area within a national park, and there is no evidence of an immediate threat or of a population decline. However, its extremely limited range makes it vulnerable to any threat that might arise in the future, e.g. climatic change or introduction of invasive species; it is therefore assessed as Vulnerable according to criterion D2.

Key to African Melastomateae genera

1	Calyx either truncate or with lobes not contorted, leaving the corolla exposed in bud; trees or shrubs with 4-merous flowers; seeds often provided with dor-
	sal hyaline papillae
_	Calyx-lobes always developed, contorted and concealing the corolla in young
	bud stage; herbs, or if shrubs then flowers always 5-merous; seeds tuberculate,
	smooth, ridged or foveolate, without hyaline papillae2
2	Flowers involucrate, solitary or in heads; calyx-lobes persistent; intersepalar
	appendages absent; fruits capsular or baccate
_	Flowers not involucrate (except in Dissotis speciosa), solitary, glomerulate,
	panicled or racemose; calyx-lobes caducous or persistent; intersepalar ap-
	pendages present; fruits capsular or irregularly dehiscent, never baccate5
3	Shrub with 1-flowered inflorescences; stamens isomorphic, with two ventral
	and one dorsal appendage, no distinct pedoconnective and erect anthers
_	Herbs, or if shrubs then flowers several per inflorescence; stamens not as
	above, with two ventral appendages only, and pedoconnective usually well-
	developed4
4	Fruit fleshy, baccate; stamens isomorphic (except <i>T. cornifolium</i>), with erect
	anthers; hypanthium with hairs often arranged in rings (but sometimes gla-
	brous or hairy all over)
_	Fruit dry, capsular; stamens heteromorphic (except M. porteresii), with an-
	thers patent or curved; hypanthium glabrous or with hairs not arranged in
_	rings
5	Stems, leaves, and inflorescences with stellate hairs, sometimes with simple
	hairs present as well; leaves sessile, amplexicaul
_	Stems, leaves and inflorescences with simple or dendritic hairs, or sometimes
	glabrescent; leaves usually petiolate6
6	Shrubs
_	Herbs, sometimes ± woody at base
7	Calyx-lobes notched at apex, asymmetrical, caducous; leaves deciduous
	Nothodissotis
_	Calyx-lobes entire, ± symmetrical, caducous or persistent (always persistent if leaves deciduous)
	reaves deciduous)

8	Intersepalar appendages absent or reduced to a bristle; calyx-lobes persistent;
	hairs on stems and leaves ± bulbous at base; leaves deciduous or not9
_	Intersepalar appendages well-developed; calyx-lobes caducous (sometimes
	tardily so); hairs on stems and leaves not bulbous at base; leaves never
0	deciduous 10
9	Inflorescence a 1–3(–7) flowered cyme; intersepalar appendages present; sta-
	mens isomorphic; leaves small, $1.5-2.5 \times 1-1.5$ cm
_	Inflorescence a many-flowered panicle; intersepalar appendages absent; sta-
10	mens usually dimorphic; leaves much larger
10	Anthers isomorphic, opening by an extrorse pore; leaves distinctly bicoloured,
	dark green above and yellowish-green beneath
_	Anthers usually dimorphic, opening by an introrse pore; leaves not as above
11	
11	Calyx-tube accrescent in fruit, developing a long neck with longitudinal ribs;
	intersepalar appendages absent; stamens dimorphic
_	
	ribs; intersepalar appendages usually present; stamens dimorphic or isomorphic
12	Seeds longitudinally ridged or foveolate, with a (sometimes very short) basal
12	aril; stems creeping at base; staminal appendages bilobed or bipartite in outer
	stamens; hypanthium with stalked stellate emergences (except <i>H. decumbens</i>
	with simple hairs)
_	Seeds tuberculate or smooth, not arillate; stems usually erect, or if creeping
	(Guyonia), then staminal appendages entire in outer stamens; hypanthium
	usually glabrous or with simple hairs (in <i>Antherotoma</i> sometimes with stellate
	emergences)
13	Seeds with parallel rows of tubercles; staminal appendages bilobed or bipartite;
-0	flowers 4- or 5-merous; calyx-lobes persistent or caducous; hypanthium with
	simple eglandular hairs or stellate emergences, rarely glabrous (Chaetolepis
	gentianoides)
	D. sect. Dissotis, D. congolensis, D. tubulosa, African "Osbeckia")
_	Seeds smooth, or with tubercles not arranged in parallel rows; staminal ap-
	pendages entire in the outer whorl at least; flowers usually 5-merous (4-mer-
	ous in Guyonia rupicola) calyx-lobes always persistent; hypanthium glabrous
	or with glandular hairs, rarely (Guyonia pygmaea) with simple eglandular
	hairs14
14	Stems thick and fleshy, winged, erect; hypanthium with prominent longitudi-
	nal nerves; inflorescence an elongate cyme (raceme) with two well-developed
	bracts under each flower; plant almost glabrous except the ciliate leaves and
	calyx
_	Stems slender, usually not winged, creeping or more rarely erect; hypanthium
	with nerves hardly distinct; inflorescence not as above, usually with very small
	bracts, often 1-flowered; plant glabrous to densely hairy

Acknowledgements

We are grateful to the curators and personnel of the following herbaria (BR, BRLU, C, EA, MO, WAG, K and UPS) for providing loans and assistance during visits. We would also like to thank Doris Franke for preparing the illustration, and Vincent Droissart and Tariq Stévart for their field pictures. We are grateful to Torsten Hauffe at the University of Gießen, Germany for taking photographs of the hypanthium appendages using a digital microscope (Keyence VHX-2000). We would like to thank Ricardo Kriebel, Fabián Michelangeli and an anonymous reviewer for their help in improving this article. This study is part of a larger project on African Melastomateae supported by the International Association for Plant Taxonomy (IAPT), German Research Foundation (DFG) project number KA1816/10-2, Equal opportunity travel grant, University of Mainz, Germany and the German Academic Exchange Service (DAAD).
