Abstract

The composition of many Chenopodiaceae genera in different parts of Himalaya and Tibet has been insufficiently known or contradictory. A revision of the family in Himalaya including Bhutan, Nepal, parts of India (Himachal Pradesh, Jammu and Kashmir, Sikkim and Uttarakhand) and Tibet (Xizang, China) is presented for the first time. Altogether, 57 species from 20 genera are reported, including three species new to science (*Agriophyllum tibeticum*, *Salsola austrotibetica* and *Salsola hartmannii*). *Atriplex centralasiatica*, *Corispermum dutreuilii* and *Salsola monoptera* are identified as new records for India and *Chenopodium pamiricum* is recorded in China for the first time. *Dysphania ambrosioides* and *Sympegma regelii* are recorded for Xizang. The generic and species keys, species distributions (including maps) and taxonomic notes are provided. We indicate for the first time that the presence of short yellow hairs is the remarkable morphological characteristic of the genus *Grubovia*. Evident heterocarpy and heterospermy is found in *Dysphania* for the first time (*Dysphania tibetica*). *Agriophyllum pungens*, *Atriplex crassifolia*, *Atriplex laciniata*, *Atriplex sagittata*, *Axyris amaranthoides*, *Axyris hybrida*, *Bassia indica*, *Corispermum korovinii*, *Dysphania schraderiana* (=*Chenopodium foetidum* auct.), *Halocharis violacea* and *Suaeda microsperma* are excluded from the species list. *Neobryndium corniculatum* is synonymised with *Dysphania kitiae*, *Neobryndium longii* with *Dysphania himalaica* and *Neobryndium ornithopodum* seems to be conspecific with *Dysphania nepalensis*. *Corispermum ladakhianum* is a new synonym of *Corispermum tibeticum*. *Amaranthus diandrus* is added to the synonyms of *Acroglochin persicarioides*, and *Bassia fiedleri*, previously considered as conspecific with *Grubovia dasypylla*, is added to the synonymy of *Bassia scoparia*. Lectotypes of *Anabasis glomerata* (=*Halogeton glomeratus*), *Halogeton tibeticus* (=*Halogeton glomeratus*), *Amaranthus diandrus* (=*Acroglochin persicarioides*), *Chenopodium tibeticum* (=*Dysphania tibetica*), *Corispermum dutreuilii*, *Corispermum falcatum*, *Corispermum lhsaense*, *Corispermum pamiricum* var. *pilocarpum* (=*Corispermum gelidum*, syn. nov.), *Corispermum tibeticum*, *Kochia indica*

(\equiv *Bassia indica*), *Kochia odontoptera* (\equiv *Bassia odontoptera*) and *Salsola monoptera* are selected. Out of 53 native elements, 42 are restricted in their distribution to Himalaya and Tibet at altitudes 2000–4500 m above sea level. The greatest taxonomic diversity of the Chenopodiaceae is represented in Jammu and Kashmir (India) and Xizang (China) with a continuous decrease in the number of species southwards.

Introduction

The family Chenopodiaceae is one of the most difficult groups of flowering plants in terms of its taxonomy and diagnostics. In the last two decades, our knowledge of

the relationships in the family, its placement within the order Caryophyllales and the physiological or anatomical peculiarities of its species have greatly increased. However, there have only been a limited number of taxonomic revisions of the family based on recent taxonomy and critical analysis of collections.

Taxonomy and generic delimitation

The Chenopodiaceae is a part of the large Chenopodiaceae-Amaranthaceae clade within the core order of Caryophyllales and it is a sister group to the Amaranthaceae family (Cuénoud et al. 2002, Kadereit et al. 2003, Brockington et al. 2009). Although all morphological characters seem to overlap in Chenopodiaceae and Amaranthaceae s. str., the familial status of the Chenopodiaceae is accepted in recent taxonomic treatments (e.g. Sukhorukov 2014, Hernández-Ledesma et al. 2015). The carpological differences that have been discovered (Sukhorukov et al. 2015a) have filled the gaps in the character set of both Chenopodiaceae and Amaranthaceae s. str., but they are not strongly specific at the familial level except the horizontal embryo position which evolved in many Chenopodiaceae.

When separated from Amaranthaceae, the Chenopodiaceae includes ~100 genera and 1600 species that are mostly distributed in the deserts and steppes in the temperate regions of the world (Sukhorukov 2014). During the last fifteen years, the generic composition of many groups in the family has undergone extensive changes following molecular phylogenetic revisions, with the splitting or merging of many genera. *Chenopodium* was found to be polyphyletic and its members occupy different phylogenetic positions within Chenopodioideae (Fuentes et al. 2012; Sukhorukov et al. 2018). In the previous broader sense, *Salsola* appeared to be strongly polyphyletic (Akhani et al. 2007), but in contrast, the formerly accepted genus *Kochia* is now merged with *Bassia* (Kadereit & Freitag, 2011). The monophyly of many other traditional genera, e.g. *Agriophyllum* (Kadereit et al., 2003), *Suaeda* (Schütze et al., 2003), *Atriplex* except *Halimione* (Kadereit et al., 2010), *Corispermum* (Xue & Zhang, 2011) and *Dysphania*, including *Neobotrydium* and *Ambrina* (Uotila et al. in prep.) is confirmed.

Subsequently, the generic status of some groups in Tibet and Himalaya has been changed compared with previous taxonomy accepted in many floristic works including comprehensive treatments of the family in adjacent territories like “Flora Iranica” (Rechinger 1997), “Flora of Pakistan” (Ali and Qaiser 2001), as well as “Flora of China” (Wu and Raven 2003) that encompasses a part of the territory under study. Of all the known Chenopodiaceae species in the study area, only the position of *Haloxylon thomsonii* is still pending within the tribe Salsoleae and its placement with tree-like species within the Saharo-Arabian and Irano-Turanian genus *Haloxylon* may be incorrect due to differences in life history and stem anatomy (Sukhorukov, unpubl.).

Progress towards disentangling the generic composition of Chenopodiaceae in Himalaya and Tibet began with the critical revisions and additions to *Axyris* (Sukhorukov, 2011), *Dysphania* (Sukhorukov 2012, 2014, Uotila 2013, Sukhorukov et al. 2015b, Nobis et al. 2015, 2017) and part of *Chenopodium* s. str. (Sukhorukov and Kushunina 2014, 2015).

Study premise

The most recent taxonomic revision of the Chenopodiaceae was performed for Nepal (Sukhorukov and Kushunina 2014), but the species composition of some genera and their distributions are still insufficiently known in other parts of the entire Himalayas and Tibet. The latest Chenopodiaceae treatment for India (Paul 2012) contained many taxa that are, in fact, distributed only in Central Asia (e.g. *Atriplex crassifolia*, *Axyris amaranthoides*, *Chenopodiastrum hybridum* and *Suaeda microsperma*), Eastern Europe/North Kazakhstan (*Atriplex sagittata*) or the Mediterranean (*Atriplex rosea*). Taxonomic novelties to the chenopodiaceous flora of China were provided by Zhu and Sanderson (2017) and some new species (i.e. *Neobotrydium corniculatum*, *N. longii*) were also reported from Xizang. All these taxa reported from India or China are discussed in our article.

The present revision is a part of the treatment of the family in the Old World. Until now, the Chenopodiaceae had been revised for the flora of European Russia (Sukhorukov 2014), Iraq (Sukhorukov et al. 2016) and historical Palestine (Danin et al. in press). In addition to Himalaya and Tibet, further contributions are planned for all of Africa, Russia and Uzbekistan.

Materials and methods

Choosing the study territory

Geographically, the Himalayan Mountains and the Tibetan Plateau (sometimes called Pan-Himalaya) encompass a large territory bordered by the Karakoram Range to the north, the Indian plate to the west, the Central China plain to the east and Mainland Southeast Asia to the south. The territory included in the present investigation (Fig. 1) covers most parts of Himalaya and the Tibetan Plateau within the following countries: Bhutan, Nepal, parts of China (Xizang or the Tibet Autonomous Region) and India (states of Uttarakhand, Himachal Pradesh, Sikkim and Jammu and Kashmir, excluding the politically disputed territory in North Jammu and Kashmir with a poorly investigated flora that is probably rich in Central Asian species). Arunachal Pradesh (India) is not included in this treatment due to an absence of specimens seen. This treatment is a major contribution to Chenopodiaceae under the project “Flora of Pan-Himalaya”.

Figure 1. The territory included in the present investigation (highlighted in green). Abbreviations: 1 – Sikkim.

Materials investigated

The field investigations were conducted by Alexander Sukhorukov in different provinces of Nepal in 2005 and 2008–2015 and in Dehradun and its surroundings in 2018 (Uttarakhand, India). The main collection is in MW with duplicates in B, BM, BR, E, G, H, K, M and W. The revision of the herbarium material was undertaken by the first author (AS) at B, BM, BR, BSD, DD, E, G, H, HUJ, K, KATH, L (including U and WAG), LE, LY, M, MHA, MSB, MW, P, PE, PRA, SHI, TO, TUCH, W, WU, WUK, XIA and XJBI (herbarium abbreviations according to Thiers 2018+) and the *Axyris* and many *Dysphania* specimens were revised by the first author in CAL in 2011. The Chinese Virtual Herbarium (CVH, <http://www.cvh.ac.cn/>) and the herbarium database of the Kunming Institute of Botany of the Chinese Academy of Sciences (Kingdonia, <http://db.kun.ac.cn/>) were used as citations for some specimens kept in HNWP, NAS and KUN if their identification were possible using the images. The great number of examined specimens was mostly provided by the following collectors or collection teams.

Adolph, Hermann and Robert Schlagintweit. Expeditions to Himalaya 1854–1857 including West/Central Himalaya, Tibet and adjacent territories (Büchler 1990). Many interesting facts about the lives of these brothers, their relationships with other botanists and the destiny of their herbarium can be found in the book by von Brescius et al. (2015). The examined collections are available from the year 1856 in the BM, E, G and LE herbaria.

Thomas T. Thomson. Expeditions to West Himalaya, Tibet and then to Sikkim (Woodward 1898). Chenopodiaceae collections are available from 1845 and

1847–1848, mostly from North India (Jammu and Kashmir, Himachal Pradesh and Uttarakhand). The sheets often labelled as “collected in Thibet occ.” [West Tibet] were probably collected in West Himalaya (former British India), but without precise locations, therefore these records could not be mapped.

Walter Koelz. Expeditions to North India (Jammu and Kashmir). Although the main goal of the expeditions was ornithology, he gathered many plant species including Chenopodiaceae. The collections, kept at the herbarium of Michigan University (n.v.), are also stored in herb. P (1930; Himachal Pradesh) and dispersed in E, G, H, K, L, LE and W (1931, 1933; Jammu and Kashmir).

Francis Ludlow (often collected together with **George Sherriff** and other scientists). The Tibetan and North Himalayan collections are available from 1928, 1939, 1940–1943 in BM and E with some duplicates in G and LE. The explorations of F. Ludlow and G. Sheriff are described by Fletcher (1975).

Andrew John Charles Grierson and David Geoffrey Long. Their joint collections of Chenopodiaceae are from Bhutan (1979, 1982, 1984) and are kept in Edinburgh (E) with duplicates in Kew (K). Additionally, D.G. Long collected some material in Nepal (1991–1992, kept in E).

Hans Hartmann. Worked in Jammu and Kashmir (India) and adjacent territories from 1976 until 1997; the Chenopodiaceae collections are available from 1976, 1979, 1992, 1995 and 1997 in G and MSB.

Brij Mohan Wadhwa. Had special interest in the Chenopodiaceae of Indian Himalaya. His collections from Jammu and Kashmir (1976 and 1986) and Himachal Pradesh (1974) are mostly kept in BSD.

Upendra Chandra Bhattacharyya. Collected many Chenopodiaceae taxa in India: Jammu and Kashmir (1970, 1980), Himachal Pradesh (1970–1972) and Uttarakhand (1961, 1970, 1983). His collections are deposited in BSD.

Georg and Sabine Miehe. Mostly worked in Tibet (Xizang, China) from 1977 to 2005. The main collections are in Marburg (“High Asia Project Herbarium G. & S. Miehe”, Faculty of Geography, University of Marburg, Deutschhausstr. 10, D-35032 Marburg, Germany). The herbarium does not have an acronym. Instead, “herb. Miehe” was used when citing their specimens in this paper.

Bernhard Dickoré. Worked in Tibet (Xizang) in 1989, 1994 and 1998. The main collections are in Munich (MSB with some duplicates in K and KAS). Some specimens were not seen by the first author (A.S.) during his visit to Munich in May 2016.

Leos Klimes (Leosh Klimesh). Collections available from Ladakh, North India, collected in 1989 (MSB) and 1999–2007 (PRA). He has been missing in Ladakh since September 2007. His collections in PRA are the most complete recent specimens of Chenopodiaceae from Ladakh. However, not all specimens are present or mounted in PRA (pers. comm. Jan Štepanek).

Tibet Chinese Herbal Medicine Survey Team. Collected in Lhasa and Xigazê (Rikaze) Prefectures (Xizang) in 1972. More than 6000 collections were made and the specimens were deposited in PE and HNWP. Collectors on this team in-

cluded Wang Jin-Ting, Lang Kai-Yong, Ma Cheng-Gong and Bao Xian-Cheng (Wang et al. 2004).

Qinghai-Tibet Complex Expedition Team, abbreviated **Qinghai-Tibet Team**. Collected throughout Xizang in 1973–1976. The team also consisted of several subdivisions, such as the “Vegetation Group”, “Meadow Group” and “Additional Group”. In total, nearly 40000 collections on approximately 150000 sheets were made and these specimens were deposited in PE, KUN and HNWP. Collectors worked in the Team were Wu Su-Gong, Ni Zhi-Cheng, Lang Kai-Yong, Chen Shu-Kun, He Guan-Fu, Cheng Shu-Zhi, Gu Li-Min, Nan Yong, Luosangxi’nao, Xiao Yonghui, Yang Yong-Chang, Huang Rong-Fu, Tao De-Ding, Zang Mu, Yin Wen-Qing, Su Zhi-Yun, Wu Zheng-Yi, Du Qing, Yang Chong-Ren, Guan Kai-Yun, Chen Wei-Lie, Li Bo-Sheng and Wang Jin-Ting (Wang et al. 2004).

The recent collections from Nepal (2005, 2008–2015) were made by **Alexander Sukhorukov** (see above).

Preparation of the material for carpological studies

The perianth, fruit and seed characters play significant roles in the identification of some large genera, e.g. *Atriplex*, *Chenopodium*, *Corispermum* and *Dysphania* (e.g. Uotila 2001, Sukhorukov 2006, 2007a, 2007b, Sukhorukov and Kushunina 2014) and we used scanning electron microscopy (SEM) to show the important differences in the reproductive traits. The hard tissues (seed coat) do not require any special preparation prior to SEM, but other objects that contain living cells, such as hairs or papillae (on perianth or pericarp), were dehydrated in aqueous ethyl alcohol solutions of increasing concentration, then in alcohol-acetone solutions and pure acetone and then finally critical-point dried. After sputter coating the material with gold-palladium, all SEM observations were made with a JSM–6380 microscope (JEOL Ltd., Japan) in the Laboratory of Electron Microscopy of Moscow State University.

The anatomy of the fruit and seed is important for the diagnostics and taxonomy of many Chenopodiaceae (for more see, e.g. Sukhorukov 2008, 2014, Sukhorukov and Zhang 2013, Sukhorukov et al. 2013, 2014, 2015a). The fruit anatomy appears crucial to the diagnostics of many *Corispermum* and the fruits of almost all members were anatomically investigated in previous studies (Sukhorukov 2007a, 2007b, 2014, Sukhorukov et al. 2014). Here, we present the fruit anatomy of *Corispermum tibeticum* Iljin and add the most important data to the description of the species.

The list of specimens used for SEM is given below.

Chenopodium album: Nepal, Karnali zone, Jumla vill., 23 Sep 2010, A. Sukhorukov 463 (MW);
C. pamiricum: Eastern Kazakhstan, 1944, Goloskokov s.n. (LE);

- C. ficiifolium*: Central Nepal, Narayani zone, Chitwan [distr.], 4 Mar 2008, *A. Sukhorukov* s.n. (MW);
- C. karoī*: India, Jammu & Kashmir, Ladakh, Zanskar Region, S of Padum, 4150 m alt., 29 Aug 2003, *L. Klimeš* 3322 (PRA);
- C. bengalense*: Nepal, Dhaulagiri zone, Annapurna conservation area, near Tikhedhunga vill., 1700 m a.s.l., 13 Nov 2008, *A. Sukhorukov* s.n. (MW);
- C. novopokrovskyanum*: India, Jammu & Kashmir, Leh, 3400 m a.s.l., 20 Aug 1979, *Bruhn* s.n. (MSB144211);
- C. atripliciforme*: Afghanistan, Konar, Dewagal Darrah, Aug 1973, *O. Anders* 11078 (W06301);

- C. tibeticum*: 1) [Afghanistan or Pakistan] Karakoram, Aug 1876, *Falconer s.n.* (K); 2) China [Ngari Pref., Burang County], nr Manasarovar Lake, Langa Tso [Lake], 4680 m a.s.l., 29 Aug 1993, *G. & S. Miehe 9598/03* (MSB147354); 3) India, Ladakh, Pangong Region, 4300 m a.s.l., 10 Sep 2002, *L. Klimeš 10* (PRA);
- Agriophyllum tibeticum*: China, Xizang, Kongbo [Kongpo] County, Temo, Tsango valley, 8 Sep 1938, *F. Ludlow & al. 6238* (BM);
- Suaeda olufsenii*: India, Jammu & Kashmir, Ladakh, Rupshu Region, Chumur, 4660– 4860 m a.s.l., 21 Aug 2001, *L. Klimeš 1382* (PRA).

Morphological description

Where not stated otherwise, the generic and species descriptions are based on specimens of various origins. The habitats and altitudes relate to populations growing in Himalaya and Tibet.

Results and discussion

Ecology and altitudinal gradient of the Himalayan and Tibetan Chenopodiaceae

In general, the taxonomic diversity of the Chenopodiaceae is low in mountainous regions of the tropics compared with the steppes and deserts of temperate regions. The altitudes, where the Chenopodiaceae can be found, range from 0 to 5500 m above sea level. The diversity of representatives of Chenopodiaceae and their phytosociological role differ amongst three major altitudinal belts (Fig. 2).

The altitudes from 0 to 2200 m above sea level. The lower altitudes are appropriate only for several species that occupy (semi-)disturbed places. In Central and Eastern Himalaya, the annuals *Chenopodium album* and *C. ficifolium* are common ruderal and segetal plants that vegetate in late winter and spring. *Dysphania ambrosioides*, the only alien naturalised species from the tropical Americas, usually colonises dump sites along roads, but it can also be found on semi-disturbed river banks. *Chenopodiastrum murale* occupies various disturbed habitats, although its presence in Tibet and many regions of Himalaya has not yet been confirmed.

Figure 2. Typical habitats of Himalayan and Tibetan Chenopodiaceae: **A** Subtropical forest in Zham, Xigazê Prefecture, Xizang (2000 m a.s.l.) **B** Tarlung Tsangpo Valley in Nyingchi Prefecture, Xizang (3100 m a.s.l.) **C** stony desert near Jomosom, Dhaulagiri zone, Nepal (ca. 3000 m a.s.l.) **D** alpine desert in Zanda county, Ngari Prefecture, Xizang (4800 m a.s.l.). Photographs by A. Sukhorukov (**C**) and P.-L. Liu (**A, B, D**).

The altitudes from 2200 to 3500 m above sea level. Most annual Chenopodiaceae growing at these altitudes are found on the screes, on limestone or sand or often in disturbed habitats (being apophytic). In North Himalaya and Tibet, some annuals that usually grow at 3500–5000 m above sea level can be found at lower altitudes (*Chenopodium* sp. div., *Corispermum* sp. div. and *Dysphania* spp.). In Central Himalaya, 2200–3500 m is the most appropriate altitude for *Acroglochin persicarioides* and *Dysphania nepalensis*, where they are abundant, weedy species (Sukhorukov and Kushunina 2014). In West Nepal, *Chenopodium perttii* and *Dysphania neglecta* are common. Different *Chenopodium* species often grow together, e.g. *Dysphania neglecta* and *D. nepalensis* in Nepal (Fig. 3).

The altitudes from 3500 to 5000(5500) m above sea level. This altitude range constitutes a zone of alpine steppes and cold deserts (Fig. 2) where three sub-shrubby Chenopodiaceae members play a significant role as the dominants of different plant communities. *Krascheninnikovia ceratoides* (s.l.) is one of the dominants of stony plant formations of North Himalaya (Hartmann 1983, 2009) and Tibet (Namgail et al. 2012, Hong and Blackmore 2015), with local distribution in Nepal, Central Himalaya (Yonekura 2008, Sukhorukov and Kushunina 2014). Other subshrubs have limited distribution patterns in the territory under study. *Bassia prostrata* is mostly distributed in Jammu and Kashmir (India), where it can be abundant in subalpine deserts

Figure 3. *Dysphania nepalensis* (red plant) at fruiting stage and *D. neglecta* (green plant) at blooming stage. Photograph by A. Sukhorukov (Midwestern Nepal, Mugu distr., October 2014).

at altitudes of 3500–4000 m (Hartmann 2009). Another dwarf subshrub, *Haloxylon thomsonii*, is localised only in Ladakh and adjacent territories in Pakistan at altitudes of (3200)3500–4000 m, where it forms characteristic alpine semi-desert and steppe landscapes together with some *Artemisia*, *Caragana*, *Potentilla* and *Ptilotrichium* species (Dhar and Kachroo 1983, Hartmann 1983, 2009, Eberhardt et al. 2007, Gruber and Peer 2008). *Sympetrum regelii*, a common plant on the scree in Tian-Shan and Kunlun (Grubov 1966, Eberhardt et al. 2007), has been found in northwest Tibet during the last several decades.

Amongst the annuals, *Axyris mira*, *Axyris prostrata*, *Corispermum* sp. div. and some *Dysphania* (*D. himalaica*, *D. nepalensis* and *D. tibetica*) are widespread in stony deserts, river basins and disturbed areas. *Microgynoecium tibeticum*, a small, often-overlooked herb, reaches altitudes up to 5500 m, and this altitudinal zone appears to be the highest level at which only a few flowering plants are observed (Sukhorukov 2014). All Chenopodiaceae at the higher altitudes are native species growing in natural or degraded communities (Klimeš and Dickoré 2005, Miehe et al. 2009).

Taxonomy and geographical subdivision of the species

In their recent circumscriptions, 20 genera are recognised in Himalaya and West Tibet, representing all subfamilies of Chenopodiaceae and 57 species have been recorded.

The best-represented genera are *Chenopodium*, *Corispermum* and *Dysphania* (9 species each). None of the taxa can be recommended for inclusion in the IUCN Red List (IUCN 2017) since they are either dominant species, occupy ruderal habitats or are insufficiently studied.

In the past, very few species were recorded for the entirety of Himalaya and Tibet (within the borders of Xizang) and the number of Chenopodiaceae species reported for Tibet was only 15 (Grubov 1966) or 29 (Zhu et al. 2003). Fifteen species were reported for Lower Ladakh, India (Klimeš and Dickoré 2005). Here, we present the first attempt to evaluate the number of species in the main divisions of the region under study. The number of species was counted for all the countries of Bhutan and Nepal, the major administrative subdivisions of Xizang (prefectures) and the Indian states of Jammu and Kashmir, Himachal Pradesh, Uttarakhand and Sikkim (Fig. 1).

Bhutan – 9; Nepal – 25; Xizang, China – 42 species in total (Ngari Prefecture – 26, Nagqu Prefecture – 12, Xigazê Prefecture – 24, Lhasa City – 19, Shannan Prefecture – 16, Nyingchi Prefecture – 19, Qamdo Prefecture – 11); **India – 43** species in total (Jammu & Kashmir – 41, Himachal Pradesh – 21, Uttarakhand – 15, Sikkim – 6).

Although phylogeographic analysis has yet to be conducted for the Asian Chenopodiaceae, the origin and migration routes of the widely distributed taxa may be more complex than previously thought (Li et al. 2010, Jia et al. 2012, Zhang et al. 2014, 2017). However, we note here that many taxa (42%) are clearly autochthonous, distributed only or predominantly in Himalaya and Tibet (*Acroglochin persicariooides*, *Agriophyllum tibeticum*, *Axyris mira*, *Chenopodium atripliciforme*, *C. bengalense*, *C. harae*, *C. peritti*, *Corispermum falcatum*, *C. pseudofalcatum*, *C. lepidocarpum*, *C. lhasaense*, *C. nanum*, *C. tibeticum*, *Dysphania bhutanica*, *D. himalaica*, *D. geoffreyi*, *D. neglecta*, *D. nepalensis*, *D. tibetica*, *Haloxyton thomsonii*, *Microgynoecium tibeticum*, *Salsola austrotibetica*, *S. hartmannii*, *S. jacquemontii*). Many taxa (~28%) clearly demonstrate the distribution pattern across Central Asia (*Atriplex centralasiatica*, *A. pallida*, *A. pamirica*, *Axyris prostrata*, *A. sphaerosperma*, *Bassia scoparia*, *Chenopodium karoi*, *C. pamiricum*, *Corispermum dutreuilii*, *C. gelidum*, *Grubovia dasypylla*, *Halogeton glomeratus*, *Salsola collina*, *Suaeda olufsenii*, *Sympegma regelii*, *Teloxys aristata*). *Bassia odontoptera* has an Irano-Turanian origin.

Two species, *Atriplex hortensis* and *Dysphania ambrosioides*, are adventive plants (ergasophytes). The adventive status of *Chenopodium album* and *C. ficifolium* is still not confirmed.

Key to the genera

The key to the infrafamilial groups (subfamilies) and their characteristics are provided in some recent works (Sukhorukov 2014; Sukhorukov et al. 2015a, 2016b) and we chose not to repeat it in the present work. The generic key does not include *Spinacia oleracea* L. (Chenopodioideae-Anserineae), which is often cultivated as a vegetable (especially in China) and *Beta vulgaris* L. (Betoideae), which is also sometimes present in vegetable gardens. Both species have no tendency to escape from cultivation.

- 1 Plants with dendroid, branched (when main axis bears lateral outgrowths arranged one above the other) or stellate hairs (sometimes intermixed with simple hairs) covering all the plant or the young parts only..... **2**
- Plant glabrous or covered with papillae, simple, bladder ('white meal'), glandular hairs or subsessile glands **5**
- 2 Plants with stellate hairs, sometimes intermixed with long simple hairs; flowers unisexual (male inflorescence terminal; female flowers located below in the bract axils) **3**
- Plants covered with dendroid or branched hairs; simple hairs absent; flowers bisexual **4**
- 3 Plants subshrublets or subshrubs; female flowers without perianth, enclosed by two bracts that are fused at least halfway; at fruiting, bracts slightly enlarged and covered with long simple and short-rayed stellate hairs
- **10. *Krascheninnikovia***
- Plants annuals; female flowers with a bract and free hyaline not enlarging perianth segments covered with simple hairs **9. *Axyris***
- 4(2) Hairs dendroid (additional outgrowths are small) on the stem and branched on the leaves; leaves and bracts quickly hardened, persistent; fruit dehiscent in the lower half..... **13. *Agriophyllum***
- Hairs branched (lateral outgrowths large); leaves and bracts not hardened, partially caducous; bracts of the same consistency; fruit indehiscent
- **12. *Corispermum***
- 5(1) Plants covered (usually densely) with straight (sometimes with curved) simple multicellular hairs; the majority or all hairs 2.0–7.0 mm long..... **6**
- Plants glabrous or with diverse types of indumentum; if long hairs present, they are clearly curved..... **7**
- 6 Stem and leaves covered with large horizontally spreading white hairs (which often turn brownish after drying) and short (up to 0.3 mm), scattered, bright-yellow hairs; leaves terete, fleshy; fruits with star-like subulate spines; annual tumble-weed..... **16. *Grubovia***
- Stem and leaves covered with (semi)appressed or obliquely directed white hairs; bright-yellow hairs absent; fruits with wing-like or tuberculate outgrowths, rarely without any projections; annuals, subshrubs or subshrublets
- **15. *Bassia***
- 7(5) Leaves subulate or semi-terete, stout or fleshy; seeds with scant or no perisperm; embryo coiled
- **8**
- Leaves flat; seeds with abundant perisperm; embryo horseshoe-shaped or annular
- **12**
- 8 Plants subshrubs or subshrublets
- **9**
- Plants annuals
- **10**
- 9 Sub-shrublet with several pairs of opposite leaves in the lower part of the stem and alternate leaves in the upper part and in the inflorescence **19. *Haloxylon***
- Subshrub with alternate leaves (only bracts opposite)
- **20. *Sympegma***

- 10(8) Leaves fleshy, not mucronate or with a tiny mucro; bracteoles small, white; perianth with short conical outgrowths; seeds heterospermous (dark red and brown)..... **14. *Suaeda***
- Leaves (or at least bracts) fleshy or stout, with caducous or persistent mucro; bracteoles green or with reddish stripes, similar in shape to the bracts; perianth segments mostly with short or clearly visible wings at the fruiting stage; seed covers transparent (whitish) **11**
- 11 Leaf mucro falls off easily (sometimes all leaves with reduced or hardly noticeable mucro); seed embryo vertically orientated..... **18. *Halopegeton***
- Leaf mucro always persistent, not caducous; seed embryo horizontally or obliquely orientated **17. *Salsola***
- 12(7) Plants usually aromatic, covered with different sets of trichomes (simple and/or white glandular hairs) and yellow or orange glands (glands are sometimes very scattered and the pubescence mostly consists of simple hairs, as in *Dysphania tibetica*)..... **7. *Dysphania***
- Plants without strong aromatic scent, glabrous or with white (sometimes with brown) bladder hairs or short and curved simple hairs; rarely, yellowish glandular hairs are present in the inflorescence **13**
- 13 Leaves short (up to 3.0 cm)..... **14**
- Leaves (at least lower ones) longer than 3.0 cm **15**
- 14 Flowers unisexual: male flowers with perianth and female flowers subtended by a leaf-like bract; pericarp forms easily visible ear-like outgrowths, at least in the upper part of the fruit; plant green, glabrous or sparsely farinose **5. *Microgynoecium***
- Flowers bisexual with perianth consisting of 5 segments; pericarp papillate (reticulate in dry fruits) or almost smooth without ear-like appendages; plant greyish-farinose **1. *Chenopodium* (part)**
- 15(13) Leaves sessile or subsessile, cuneate, entire, mostly curved ventrally.... **8. *Teloxys***
- Leaves clearly short- or long-petiolate, at least lower leaves not entire **16**
- 16 Branches with acicular apices (rarely without them); leaves glabrous or with simple short hairs with small mucronate teeth; fruits dehiscent by a lid **11. *Acroglochin***
- Branches without acicular apices; leaves without mucro; if present, hairs of other shape; fruit indehiscent or pericarp ruptures irregularly **17**
- 17 All or most flowers unisexual; male (and bisexual, if present) flowers with small hyaline actinomorphic perianth; each female flower subtended by bract-like cover consisting of two ± accrescent segments **4. *Atriplex***
- All or almost all flowers bisexual; perianth actinomorphic, not accrescent **18**
- 18 Plant with basal (“rosulate”) and cauline leaves; perianth segments at fruiting red and fleshy; pericarp tightly adhering to the seed coat; seeds ovoid **6. *Blitum***
- Plant with cauline leaves only; perianth segments green or hyaline, not fleshy; pericarp not tightly adherent to the seed and ruptures or separates easily; seeds depressed globular, rarely ovoid..... **19**

- 19 Plant prostrate or with ascending stems; perianth of 3–5 segments; pericarp smooth; seeds with both horizontally and vertically orientated embryo on the same plant **3. *Oxybasis***
- Plant with prominent erect stem; perianth of (4)5 segments; pericarp papillate (often reticulate or smooth when dry); seeds with horizontally orientated embryo **20**
- 20 Leaves slightly cordate at base; seed diameter 1.5–2.0 mm; yellowish glandular hairs present in the inflorescence.....
..... **2. *Chenopodiastrum* (*C. badachshanicum*)**
- Leaves cuneate or broadly truncate; seed diameter less than 1.5 mm; yellowish glandular hairs absent **21**
- 21 Inflorescence short (usually up to 10 cm), leafy; seeds prominently keeled; leaves rhombic, dentate or erose-dentate; plants growing below 2000 m a.s.l.....
..... **2. *Chenopodiastrum* (*C. murale*)**
- Inflorescence mostly larger and often leafless; seeds keeled or not; leaves tribolate, dentate or entire; plants growing at various altitudes.....
..... **1. *Chenopodium* s. str.**

Subfam. Chenopedioideae

Tribe Chenopodieae

1. *Chenopodium* L.

Type. *Chenopodium album* L. (typ. cons. prop.)

Notes. A formal proposal to conserve the name *Chenopodium* L. with the type *Chenopodium album* L. has only recently been put forward (Mosyakin 2015). The conservation of the name with this type would be most desirable to maintain the recent taxonomy of *Chenopodium* and its relatives, especially *Oxybasis*.

Description. Annuals, shrubs, or rarely small trees, covered with bladder hairs. Leaves petiolate, usually lobed or dentate (sometimes entire), very rarely semi-terete. Inflorescences paniculate, composed of small cymose clusters. Flowers sessile and pedicellate, hermaphrodite or some female. Perianth segments 5 (rarely 4), free or basally concrecent, green and unchanging at fruiting. Stamens usually 5, free or basally connate. Stigmas 2, free. Fruit depressed globular, falling off separately or together with perianth. Pericarp mostly thin, hyaline, of 1–2(3) parenchymatous layers, usually with small cylindrical or conical papillae (in dry fruits, the pericarp surface resembles honeycombs, but after soaking, the papillae retrieve their shape). In some species now transferred from *Einadia* to *Chenopodium*, the pericarp (at least in most fruits) is fleshy (berry), coloured, and many-layered, but some of the fruits remain dry (heterocarpy). Seeds black or rarely brown with horizontal embryo; the cell walls of testa (outer seed-coat layer) cells in black seeds with vertical stalactites, rarely the stalactites absent (three species from Juan-Fernández Archipelago).

In its current circumscription (Fuentes et al. 2012), the genus comprises more than 100 species, but the exact number is still unknown. The species are mostly distributed in extratropical parts of the world or in mountainous regions of the tropics.

Key to the species

- 1 Plant usually robust, up to 2.5 m tall; young leaves trilobate, mature leaves up to 25(30) cm long.....6. *C. bengalense*
- Plant 15–80(100–200) cm; leaves much smaller.....2
- 2 Leaves lobate with the terminal lobe two to four times as long as the lateral ones.....3. *C. ficifolium*
- Leaves without lobes or lobate; in the latter case, the apical lobe slightly (up to two times) or not larger than the lateral ones3
- 3 Seeds evidently dimorphic: dark-red to blackish, subspherical, marginally keeled and brown, flattened and marginally rounded; one of the types often predominates on the plant2. *C. pamiricum*
- All seeds black.....4
- 4 Inflorescence “spiciform” in appearance (branches with loosely arranged clusters of 2–4 flowers); leaves triangular, basally truncate or broadly cuneate, blades not lobate.....8. *C. atripliciforme*
- Inflorescence not spiciform, clusters prominent, of 4–10 flowers5
- 5 Plant prostrate to ascending; leaves mostly entire, rhombic or slightly trilobate with indistinct lateral lobes.....5. *C. karoii*
- Plant (sub)erect; at least the lower leaves dentate or lobate6
- 6 Leaves truncate or slightly cuneate; at least middle and upper leaves lobate, middle lobe gradually tapering; pericarp almost smooth when dry and with minute papillae in fresh fruits or after soaking; seeds with distinct keel.....9. *C. perttii*
- Leaves cuneate, without lobes or only slightly lobate; pericarp papillate, rarely mamillate or almost smooth; seeds without keel or with indistinct keel7
- 7 Leaves (at least abaxially) white farinose.....7. *C. novopokrovskyanum*
- Leaves green or greyish.....8
- 8 Leaves not fleshy, rhombic to lanceolate, long-petiolate, not fleshy, abaxially green or greyish.....1. *C. album*
- Leaves fleshy, oblong, short-petiolate (petioles to 1 cm), abaxially grey4. *C. harae*

1. *Chenopodium album* L., Sp. Pl.: 219 (1753)

Chenopodium album L., Sp. Pl.: 219 (1753). **Lectotype** (designated by Brenan 1954): Herb. Linn. 313.8 (LINN! image of the lectotype available at <http://linnean-online.org/3082/>).

≡Botrys alba (L.) Nieuwl., Am. Midl. Naturalist 3: 276 (1914).

Taxonomic notes. The description of the species is based on the most characteristic features of the populations growing in West/Central Himalaya; this aggregate still requires further investigations in our territory and other parts of Eurasia. A strange specimen was seen from Ladakh (Zanskar, Tsarap, Kuru Village to Tetha Village, 3950 m alt., 21 Aug 2004, 33°10'18"N, 77°10'32"E, L. Klimes 4163, PRA) bearing a small (up to 15 cm) plant with entire, ovate leaves up to 2 cm, a small inflorescence up to 5 cm long and pitted seeds that may represent a new taxon. Some plants of *C. album* from India are characterised by smooth pericarp, a trait of *C. perttii*, although they differ from the latter taxon in leaf shape.

Description. Annual, up to 150 cm, erect, branched, green. Leaves up to 10 × 4 cm, rhombic, oblong or lanceolate, entire or dentate, lower leaves often 3-lobed (terminal lobe tapering to apex). Inflorescence leafy or not. Flowers in glomerules arranged in loose inflorescence. Perianth farinose or glabrous. Fruit 1.3–1.5 mm, pericarp papillate (papillae up to 80 µm), can be scraped off the seed; seeds obtuse or acutish on margins, nearly smooth with shallow radial furrows (Fig. 4A, B), with structural heterospermy expressed in different thickness of the seed-coat testa.

Habitat. Disturbed areas; 0–4500 m a.s.l. The most common chenopodiaceous species in Himalaya and Tibet.

Phenology. Flowering: March-September; fruiting: April-November.

Distribution. See Fig. 5.

Specimens examined. **BHUTAN:** Charithang, Aug 1938, *B.J. Gould* 1396 (DD); Byakar, 27°33'N, 90°44'E, 2700 m a.s.l., 9 Jun 1979, *A. Grierson & D. Jest* 71-18 (E00214371).

General distribution. Subcosmopolitan.

2. *Chenopodium pamiricum* Iljin, Fl. SSSR 6: 873 (1936)

Holotype. [TAJIKISTAN] Pamir Orientale, declivia ad confluentes Baital et Murgab [Bartang], [East Pamir, slopes near confluence of Baital and Murgab rivers], 1 September 1923, *H. Raikova* 417 (TASH – photo seen (!) and fragments of type material (!); isotype – LE!).

Taxonomic notes. Morphologically, *C. pamiricum* can be easily confused with *C. vulvaria*, but all data on the presence of *C. vulvaria* in mountainous regions of Central Asia belong to *C. pamiricum*. In contrast to the latter species, either fresh or dry leaves of *C. pamiricum* do not have a scent. Further investigations have shown that the type material and many other specimens of *C. pamiricum* have evident heterosperry, a rare characteristic in *Chenopodium* s. str. discovered by Sukhorukov and Zhang (2013).

Description. Annual up to 25 cm with several or numerous prostrate or ascending stems. Leaves farinose, shortly petiolate (petioles up to 1.5 cm but usually much smaller) with blades up to 2 cm, rhombic or ovate, entire or sub hastate. Inflorescence leafy almost to the top. Flowers in glomerules arranged in ± dense inflorescence. Perianth farinose. Fruits and seeds heteromorphic. The first type of fruits and seeds is formed in terminal flowers, the fruits ripen in July-August. These fruits are ca. 1 mm in diameter and 0.5 mm thick; pericarp with papillae up to 20(25) µm (Fig. 4C); seed dark red or blackish with median keel (Fig. 4E, F), testa 17–25 µm thick. Fruits of the second type (which dominates at the end of the vegetation period) are ovoid, 1.0–1.2 mm long, ca. 0.5 mm thick, pericarp papillate or not (Fig. 4D); seeds yellow-brownish, elongated.

Habitat. Sandy or rocky places, 3400–5000 m a.s.l. (in Himalaya) and at lower altitudes in Central Asia.

Phenology. Flowering: June-September; fruiting: August-October.

Distribution. See Fig. 5.

Specimens examined. CHINA (new records for China): Xizang: Ngari Prefecture: Gégyai (Geji) County, Yanhu Distr., 4450–4500 m a.s.l., 24 Aug 1976, *Qinghai-Tibet Team Vegetation Group* 13541 (PE00235028); Rutog (Ritu) County, Rabang (Rebang), 4360 m a.s.l., 28 Aug 1976, *Qinghai-Tibet Team Vegetation Group* 13653 (PE00235010).

Klimeš* 3463 (PRA); Shyok (E), Laga vill., 4220–4230 m a.s.l., 12 Sep 2003, *L. Klimeš* 2745 (PRA); Indus valley, Sham (W), Basgo to Nye, 3490–3590 m a.s.l., 7 Aug 2006, *L. Klimeš* 6712 (PRA).

General distribution. Central Asia south to North Himalaya and North Tibet. For a long time, *C. pamiricum* has been considered endemic to Pamir (Ilijin 1936, Pratov 1972). The analysis of the material collected in the fruiting stage proved that the range of *Chenopodium pamiricum* covers almost all parts of Central Asia with records in Mongolia, West China (Xizang and Xinjiang), North Pakistan, North India, Kyrgyzstan, Tajikistan, Russia (Altay Mountains) and Eastern Kazakhstan. The records from Pamir, Karakoram, NW Tibet and North Himalaya represent the southernmost boundary of the distribution of *C. pamiricum*.

3. *Chenopodium ficifolium* Sm., Fl. Brit. 1: 276 (1800)

Lectotype (Al-Turki and Ghafoor 1996): figure 16 in Curtis, Fl. Londinensis 1, fasc. 2 (1778).

Taxonomic notes. The species is described from Britain: “In fimetis et ruderatis [growing on wasteland and dungheaps] about London, *W. Curtis*” (Smith 1800). The material cited in the protologue by Smith (1800) is probably lost. The specimen col-

lected in England [Yarmouth, Sep 1801, Mr. D. Turner] and kept at LINN-HS (sheet 459.24) is not a part of the original material used for the description. Citing the “type”, Al-Turki and Ghafoor (1996) refer to the drawing of Curtis (1778, fig. 16), but Curtis did not describe any *Chenopodium* in his work and erroneously labelled his fig. 16 as “*Chenopodium viride*”, although the image of the plant completely corresponds with *Chenopodium ficifolium* later described by Smith (1800). Citing the type of *Chenopodium ficifolium*, Al-Turki and Ghafoor (1996) have unintentionally lectotypified the species with the drawing in Curtis (1778). The chosen lectotype shows the plant with clearly trilobate leaves with prominent and elongated middle lobe (*Chenopodium ficifolium* subsp. *ficifolium*: Uotila 1997, 2001).

Description. Annual up to 60(80) cm, loosely branched, stem green but often with red stripes. Leaves bright green, long-petiolate, 2–7 × 1–3 cm, three-lobed; apical lobe 2–4 times longer than lateral lobes; lateral lobes in the lower part of leaf short, entire or sinuate; apical lobe long, narrow with ± parallel margins, entire or irregularly sinuate-dentate. Inflorescence leafy in the lower and middle parts, short (up to 15 cm). Perianth green, enclosing the fruit; dorsal segments slightly carinate. Fruit 1.2–1.5 mm in diameter, pericarp separating from the seed, papillate (honeycomb-like when dry). Seed marginally rounded or slightly keeled; testa longitudinally striate (Fig. 4G, H), slightly sinuate in cross-section.

Habitat. Disturbed places, river-sides, sands; 0–2200(3000) m a.s.l. Common at least in many parts of Nepal and Bhutan. Numerous seedlings were observed by AS near Mussoorie (Uttarakhand, India) in mid-February 2018.

Phenology. Flowering: February-May; fruiting: April-June. At higher altitudes (where the plant is rare), the blooming and fruiting times appear to be much later.

Distribution. See Fig. 6.

Specimens examined. **BHUTAN:** Torsa valley, Jan 1912, *anonym* s.n. (E00168226); Samchi Distr., Samchi [Samtse], 500 m a.s.l., 27 Feb 1982, *A. Grierson & D. General distribution. Widespread in the tropical submountainous territories of SE Asia (e.g. China, Myanmar), where it may be native. Rarely found in the temperate climates of Eurasia and America.

4. *Chenopodium harae* Sukhor., Phytotaxa 226(3): 290 (2015)

=*Chenopodium pallidum* sensu Sukhorukov (in Sukhorukov and Kushunina 2014), non Moquin-Tandon (1840).

Holotype. NEPAL, [Dhaulagiri Zone], Mustang Prov. [Distr.], Annapurna Conservation area, Trekking route Jomosom-Muktinath, valley of Khali Gandaki river, between Jomosom and Kagbeni villages, riverside, 2700 m alt., 22 Sep 2009, *A. Sukhorukov* 566 (MW!).

Taxonomic notes. In the latest revision of the Chenopodiaceae in Nepal (Sukhorukov and Kushunina 2014), this species is cited as *Chenopodium pallidum* Moq., but a closer look at the authentic specimens in P has proved that all plants (collected in early blooming stage) are indeed *Atriplex pallida*, now synonymised with *A. schugnanica* Iljin (Sukhorukov and Kushunina 2015).

Description. Annual up to 40 cm with erect stem; lateral branches ascending if present. Leaves short-petiolate (petioles to 1 cm) with blades up to 2 × 1 cm, fleshy,

Figure 7. Distribution map of *Chenopodium harae* (stars) and *C. karoi* (circles).

ovate, slightly cuneate, green above, greenish below, dentate, margins often red. Inflorescence bracteate or aphyllous. Perianth green, enclosing the fruit; segments abaxially carinate. Fruit 1.3–1.5 mm, pericarp easily separating from the seed; papillae up to 25 µm. Seed blackish or reddish-black, surface striate with obtuse or acutish margin (immature seeds with acute margin) with small depression apically.

Habitat. Disturbed areas; 1500–3200 m a.s.l.

Phenology. Flowering: March–September; fruiting: April–November.

Distribution. See Fig. 7.

Specimens examined. INDIA: Himachal Pradesh: Kinnaur Distr., Shongtong, 11 Jun 1972, K.P. Janandhanan 48358 (BSD); Simla Distr., Seoni, 2 Jun 1986, P.C. Pani 80903 (BSD);

NEPAL: Midwestern: Rapti Zone: [Rolpa Distr.] Phalabang, 4500 ft a.s.l., 24 Mar 1952, O. Polunin, W.R. Sykes & L.H.J. Williams 654 (BM, LE); **Western: Dhaulagiri Zone:** Mustang [Mustang Distr.], Jomosom to Kagbeni, 22 Sep 2009, A. Sukhorukov 566 (E00757737, MW); Myagdi Prov. [Distr.], nr Dana vill., 1500 m a.s.l., 11 May 2010, A. Sukhorukov 510 (MW).

General distribution. Central and Northern Himalaya (India, Nepal, Pakistan [Gilgit: E!]).

5. *Chenopodium karoi* (Murr) Aellen, Fedd. Repert. 26: 149 (1929)

≡*C. album* subsp. *karoi* Murr, Neu. Übers. Farn & Blütenpfl. Vorarlberg 1: 97 (1923).

Lectotype (designated here by Sukhorukov): [RUSSIA] Nerczynsk [Nerchinsk], dump places, 1892, Karo 169 (G00405813!).

- =*C. prostratum* Bunge in Herder, Acta Hort. Petrop. 10: 594 (1889) nom. illegit. non Schultes (1820). The name is a later homonym (ICN, art. 53.1). **Lectotype** (Uotila and Lomonosova 2016): [RUSSIA, Saha Republic] Nizhnekolymsk, 6 July 1832, *Sharypov* 20 (LE01015991!).
- =(*C. jenissejense* Aellen & Iljin, Fl. SSSR 6: 873 (1936). **Lectotype** (Uotila and Lomonosova 2016): [RUSSIA] Yenisey Prov., Turukhanskiy Krai [Krasnoyarskiy Krai, Turukhanskiy distr.], Kureyka river mouth, 66°30'N, 87°17'E, sandy and pebbly river bank, 7 Sep 1914, *N.I. Kuznetsov & V. Reverdatto* 4102 (LE01015992! for individuals at the bottom and to the right; isolectotypes – G! LE! NS). This species was only recently synonymised with *Chenopodium karoī* (Uotila and Lomonosova 2016). However, *C. jenissejense* is quite distinct in its morphological characters and needs to be studied in detail.

Description. The species is similar to *C. album*, but plants are dark green, usually with ascendant or prostrate stems up to 25 cm. Leaves ± ovate, somewhat longer than broad, sometimes inconspicuously three-lobed. Fruit 1.1–1.3 mm, pericarp reticulate in dry fruits, soaked papillae up to 50 µm long (Fig. 8A). Seed margin obtuse, surface with sinuate furrows (Fig. 8B, C).

Habitat. Disturbed areas, rocky habitats; 2500–5100 m a.s.l.

Phenology. Flowering: May-August; fruiting: July-September.

Distribution. Common plant in many parts of Himalaya and Tibet (Fig. 7).

Specimens examined. BHUTAN: Mongar Distr., Lingmethang, 14 Jun 1992, *C. Parker* 7241 (E);

General distribution. Himalaya, Central Asia, Siberia.

6. *Chenopodium bengalense* (Lam.) Spielm. ex Steud., Nomencl. Bot., ed. 2, 1: 348 (1840)

≡*Atriplex bengalensis* Lam., Encycl. 1(1): 276 (1783). **Lectotype** (designated by Sukhorukov and Kushunina 2014): “Plante potagére des Indes [vegetable plant from India], herb. De Lamarck” (P-LA00381128!). **Epitype** (designated by Sukhorukov and Kushunina 2014): NEPAL, [Dhaulagiri zone, Myagdi distr.] Annapurna conservation area, near Tikhedhunga vill., 1700 m alt., edge of vegetable garden, 13 Nov 2008, A. Sukhorukov s.n. (MW! isoepitype W2010-0007930!). All branches of the epitype and isoepitype are from one individual.

=*Chenopodium giganteum* D.Don, Prodr. Fl. Nepal.: 75 (1825). **Lectotype** (designated by Sukhorukov and Kushunina 2014): Herb. Wallich 6952 F [N. Wallich] (K!).

=*Chenopodium album* L. subsp. *amaranticolor* H.J.Coste & Reyn., Bull. Herb. Boissier, sér. 2, 5: 979 (1905). **Type:** n.v.

≡*Chenopodium amaranticolor* (H.J.Coste & Reyn.) H.J.Coste & Reyn., Bull. Soc. Bot. France 54: 181 (1907).

Taxonomic notes. The correct name for this taxon previously known as *Chenopodium giganteum* was reinstated by Sukhorukov and Kushunina (2014), but the year of Spielmark's combination *Chenopodium bengalense* (Lam.) Spielm. in Steudel (1821) is wrong, because Spielmark considered *Chenopodium bengalense* (Lam.) Spielm. as a synonym of *Atriplex bengalense* Lam. The combination *Chenopodium bengalense* is indeed validated in Steudel (1840).

Description. Robust annual up to 2.5 m, branched from the base. Petioles of lower caducous leaves up to 10 cm, blades 10–25(30) × 5–10 cm, usually rhombic, dentate, erose or trilobate with elongated terminal lobe; middle leaves rhombic or ovate, smaller; upper leaves oblong or lanceolate, completely entire, abaxially grey; young leaves often reddish. Inflorescence whitish due to the presence of abundant bladder hairs on the branches and perianth. Fruit 1.2–1.5 mm, pericarp hyaline, adjoining to the seed coat, but separating from it when rubbed, long-papillate in fresh or even dry fruits (Fig. 8D). Seed black, ± keeled, with small crater-like micro-depressions (Fig. 8E, F).

Habitat. Edges of vegetable gardens and other places with secondary vegetation; 700–2900 m a.s.l. Cultivated as a crop but very locally.

Phenology. Flowering: June–September; fruiting: August–November.

Distribution. See Fig. 9.

Specimens examined. CHINA: Xizang: Nyingchi Prefecture: Motuo [Mêdog] County, Galasha to Shuina, 1700 m a.s.l., 18 Nov 1982, Cheng & Li 03053

NEPAL: Western: Dhaulagiri Zone: [Baglung Distr.] nr Lumsum, 8000 ft a.s.l., 10 Sep 1954, J. Stainton, W.R. Sykes & L.H.J. Williams 4315 (BM; LE); [Myagdi Distr.] between Ramche & Gram, 1800–1900 m a.s.l., 20 Aug 1972, Kanai et al. 723625 (BM); [Myagdi Distr.] Annapurna conservation area, near Tikhedhunga vill., 1700 m a.s.l., 13 Nov 2008, A. Sukhorukov s.n. (MW, W2010-0007930); **Central: Bagmati Zone:** Nuwakot Distr., Bidur, *anonym* s.n. (KATH); [Rasuwa Distr.] Dhunche, 2000 m a.s.l., 22 Aug 1972, Kanai et al. 723624 (BM).

General distribution. Himalaya and Tibet and as casual alien in some parts of Eurasia (Uotila 1997; 2001). The specimens from Eastern China labelled as *Chenopodium giganteum* (PE, see also Zhu et al. 2003) do not belong to *C. bengalense*. The easternmost records of *C. bengalense* are known from Sichuan, Guizhou, Shensi and Shaanxi provinces in China (PE!).

7. *Chenopodium novopokrovskyanum* (Aellen) Uotila, Ann. Bot. Fenn. 30: 192 (1993)

≡*C. album* L. subsp. *novopokrovskyanum* Aellen, Trudy Rostov. Obl. Biol. Obsch. 2: 3 (1938). **Lectotype** (Uotila 1993): [TURKMENISTAN] Regio Transcaspica,

Aschabad, in ruderatis [in dump areas], 25 Jun 1900, *P. Sintenis* 527 (S, isolectotypes G-DC! G75415! G75426! K! LD, LE!).

Taxonomic notes. This species was described from the deserts of Turkmenistan and the identity of the populations growing in the Central Asian plains and in the Himalayan Mountains is not obvious despite the morphological similarities. The material from Himalaya is scarce and collected in the blooming or early fruiting stages. Further investigations are needed to establish the taxonomic status of Himalayan plants named *C. novopokrovskyanum*.

Description. The species is similar to *C. album*, but the leaves are bi-coloured (green or greyish adaxially and white-farinose abaxially), narrowly oblong to lanceolate. Fruit 1.0–1.1 mm in diameter, ca. 0.6 mm thick, seed almost smooth with indistinctly polygonal ultra-sculpture and indistinct pits (Fig. 10A, B).

Phenology. Flowering: June–September; fruiting: August–October.

Distribution. See Fig. 9.

Specimens examined. INDIA: Jammu & Kashmir: Ladakh, Leh, 3400 m a.s.l., 20 Aug 1979, *Bruhn* s.n. (MSB144211); Ladakh, Sabu [Saboo village], 3680 m a.s.l., 15 Jul 1992, *H. Hartmann* 4013 (MSB137924).

General distribution. SE Europe, Central Asia, North Himalaya, Karakoram.

8. *Chenopodium atripliciforme* Murr, Magyar Bot. Lapok 1: 360 (1902).

Lectotype (Uotila 1993): AFGHANISTAN, Kurrum valley, 1879, *J.E.T. Aitchinson* 980 (G11875! isolectotypes BM000629112! C, G-BOISS! FI, K! S).

Taxonomic notes. Murr (1902) cited two distant records (Russian Far East and Afghanistan) in the protologue of *C. atripliciforme*. We agree with Uotila (1993) that the specimen from the first location (Ussuri) probably belongs to *C. bryoniifolium* Bunge, which is similar in leaf shape to *C. atripliciforme*.

Description. Annual up to 1 m, mostly branched; leaves petiolate (petioles up to 4 cm). Leaf blades triangular, basally truncate or broadly cuneate, entire to erose-dentate. Inflorescence branched, terminal and axillar, slender; clusters consisting of 2–4 flowers or rarely flowers solitary. Fruit 1.2–1.4 mm with papillate pericarp. Seed black, almost smooth with indistinct small pits (Fig. 10C, D).

Habitat. Rocky places, forest margins; (1800)2000–3300 m a.s.l.

Phenology. Flowering: June–September; fruiting: August–October.

Distribution. See Fig. 9.

Specimens examined. INDIA: Jammu & Kashmir: Baramulla, Aug 1880, *Young* s.n. (BM); Sind valley, 7500 ft a.s.l., 2 Sep 1876, *C.B. Clarke* 30934 (LE); Srinagar, in monte Shankaracharya, 1770–2000 m a.s.l., 24 Aug 1986, *K.H. Rechinger* 62146 (W1998-03383, WU021382); **Himachal Pradesh:** Simla, Aug 1849, *A. Fleming* s.n. (E); Dalhousie, 20 Sep 1874, *C.B. Clarke* 22777 (K); Simla, 7000 ft a.s.l., 1 Sep

Figure 10. SEM micrographs of *Chenopodium* seeds. **A, B** *C. novopokrovskyanum* **C, D** *C. atripliciforme* **E, F** *C. perttii*. Magnification: 50 \times (**A, C, E**), 200 \times (**B, D, F**).

Janardhanan 46510 & 46519 (BSD); **Uttarakhand:** Garhwal, Jumma area, 2800 m a.s.l., 14 Aug 1974, B.D. Nailhani 53892 (BSD); [Uttarkashi Distr.] Kalyani, 3000 m a.s.l., 13 Aug 1978, A.K. Goel 64457 (BSD); Chamoli Distr., Aug 1988, P.K. Hajra 87078 (BSD); Uttarkashi Distr., Janki Chatti, 7 Oct 1993, S.C. Majumdar & S. Singh 88100 (BSD).

General distribution. East Afghanistan, North Pakistan, North India (Jammu & Kashmir, Himachal Pradesh, Uttarakhand and Punjab).

9. *Chenopodium perttii* Sukhor., Phytotaxa 191(1): 21 (2014)

Holotype. NEPAL, [Dhaulagiri Zone] Mustang [Distr.], 13000 ft alt., at edge of field, 3 Aug 1954, J. Stainton, W.R. Sykes & L.H.J. Williams 2159 (BM000832654! isolecotype LE!).

Taxonomic notes. Morphologically, *Chenopodium perttii* resembles a Far Eastern and Siberian species, *C. bryoniifolium* Bunge, but the species have different distributions and reproductive characters (Sukhorukov and Kushunina 2014). The recently identified chromosome number for *C. perttii* is 54, so it is genetically distant from other species previously identified as *C. album* (Bohumil Mandak, pers. comm.). However, we assume that *C. perttii* is more closely related to *Chenopodium album* subsp. *yunnanense* Aellen in Handel-Mazzetti (1929). This subspecies was described from Yunnan (China) and differs by the absence of the seed keel. The lectotype of *Chenopodium album* subsp. *yunnanense* was selected in Sukhorukov and Kushunina (2014).

Description. Annual up to 1(1.5–2) m with erect, scarcely branched stem. Leaves dark green, petiolate (petioles up to 3 cm), blades 3–4 × 2–3 cm, base truncate or broadly cuneate, margins often red; lower leaves triangular, entire to lobate; middle leaves trilobate with elongated mid-lobe (less than two times as long as the lateral ones) gradually tapering to apex and slightly upward-directed lateral lobes, lobes mostly entire; upper leaves also trilobate or entire, narrowly oblong. Inflorescence green, aphyllous or rather bracteose. Fruit ~1.5 mm, pericarp separating from the seed (not easily) with minute papillae that are hardly restored after soaking, almost smooth in dry fruit. Seed prominently keeled, surface with radial striae (Fig. 10E, F).

Habitat. Disturbed places, often as a weed in crop fields; 2400–4500 m a.s.l.

Phenology. Flowering: June–September; fruiting: August–October.

Distribution. See Fig. 11.

Specimens examined. CHINA: Xizang: Ngari Prefecture: Gêrzê County, 4250 m a.s.l., Aug 1972, Li 67 (PE00510178); Xigazê Prefecture: Nyalam (Nielamu) County, Zham (Zhangmu), 13 May 1966, Zhang & Lang 3361 (PE00510187); Gyirong (Jilong) County, Gyirong (Jilong) Town, 2900 m a.s.l., 6 Jun 1972, *Tibet Chinese Herbal Medicine Survey Team* 151 (PE00510191, PE00510220); Namling (Namulin) County, Qunmo, 4000 m a.s.l., 2 Aug 1972, *Tibet Chinese Herbal Medicine Survey Team* 912 (PE00510199, PE00510219); Namling (Namulin) County, Gangba, 4000 m a.s.l., 3 Aug 1972, *Tibet Chinese Herbal Medicine Survey Team* 993 (PE00510221); Lhasa City: nr Lhasa, July 1939, H.E. General distribution. Himalaya and Tibet. Frequent or common in West Nepal.

Poorly known species

Chenopodium strictum Roth, Nov. Sp. Pl.: 180 (1821)

Type. n.v. (not present in HAL and other herbaria).

This name was previously widely used for the plants growing in Europe, Siberia, Iran and Central Asia (e.g. Iljin 1936, Kinzikaeva 1968, Lomonosova 1992, Uotila 1997). Sukhorukov (2014) discovered that the plants growing in North Himalaya

Figure 11. Distribution map of *Chenopodium perttii*.

and in Europe differ in their morphological characters and *C. betaceum* Andrž. may be the correct name for the European plants. Furthermore, *C. strictum* material from Himalaya, from where the species was described, is scarce (Jammu and Kashmir, India). Further investigations are needed to discover which plants belong under this name.

Chenopodium hookerianum Moq. in DC., Prodr. 13(2): 68 (1849)

Notes. The species was described from Nepal, ex herb. Hooker (P00606414) (see link to the specimen <https://science.mnhn.fr/institution/mnhn/collection/p/item/p00606414>) and the type material bears a plant fragment collected at the flowering stage. This name has never been mentioned in the recent floristic and taxonomic accounts except the Flora of the USSR (Iljin 1936), where it was synonymised with *Chenopodium giganteum* (=*C. bengalense*). However, the protologue of *C. hookerianum* (Moquin-Tandon 1849) and a fragment of the type specimen do not demonstrate the features of the species described by Moquin well (plant height, seed characters etc.). We are still not sure how to treat *C. hookerianum*.

Chenopodium patulum Roth, Nov. Pl. Sp.: 180 (1821)

Notes. The species was described from “India Orientalis” [East India] without a precise location. The type material was not found in any herbaria including HAL. The name is a later homonym of *C. patulum* Mérat described from France (Mérat 1812) and cannot be used according to ICN (Art. 53.1).

2. *Chenopodiastrum* S.Fuentes, Uotila & Borsch, Willdenowia 42(1): 14 (2012)

Type: *Chenopodiastrum murale* (L.) S.Fuentes, Uotila & Borsch.

Description. Annuals, glabrous or covered with bladder hairs. Leaves triangular or rhombic, petiolate, entire, dentate or lobate, rarely pinnatisect. Inflorescences spreading, mostly leafless, often with scattered yellowish glandular hairs. Flowers bisexual or female with 5 perianth segments that do not change at the fruiting stage. Perianth segments free or connate to the half of their length; midvein clearly elevated adaxially. Stamens 5. Stigmas 2. Fruit 1.2–2.5 mm in diameter; pericarp 1–2-layered with conical or cylindrical papillae, forming alveolate (in fresh fruits) or reticulate (in dry fruits) surface. Seed black, with keel or not, alveolate or punctate, sometimes with deep combs; seed-coat testa with vertical or obliquely orientated stalactites. Latent structural heterosperry expressed as varying testa thickness found in some species; seed embryo horizontal.

At least 10 species in all continents.

1. *Chenopodiastrum murale* (L.) S.Fuentes, Uotila & Borsch, Willdenowia 42(1): 14 (2012)

Fig. 12

≡*Chenopodium murale* L., Sp. Pl.: 219 (1753). **Lectotype** (designated by Brenan 1954):

Herb. Linn. 313.6 (LINN! image available at <http://linnean-online.org/3080/>).

=*Chenopodium ilicifolium* Griff., Not. Pl. Asiat. 4: 337 & Tab. 521 (1854). Described from Shikarpur, Pakistan (type n.v.).

Taxonomic notes. *Chenopodium ilicifolium* was previously synonymised with *Chenopodium botrys* (≡*Dysphania botrys*); see Press et al. (2000). Despite the absence of the authentic herbarium, we merge *Chenopodium ilicifolium* with *Chenopodiastrum murale* for the following reasons: (1) the drawings of *C. ilicifolium* (Griffith 1854) show the plant with dentate leaves, a short and leafy inflorescence, closed flowers and fruit with a papillate pericarp. These traits are characteristic of *C. murale*. Additionally, the city of Shikarpur is located on the plains where other *Chenopodiastrum* do not occur. The merger of *Chenopodium ilicifolium* with *Chenopodiastrum murale* is consistent with the opinion of Singh (2014, sub *Chenopodium murale*).

Figure 12. *Chenopodiastrum murale* plants at blooming stage. Photograph by A. Sukhorukov (Dead Sea area, Israel, February 2011).

Description. Annual, 10–50 cm, erect, with several lateral branches, slightly mealy. Leaves 2.0–6.0 × 1.0–5.0 cm, dark green, broadly deltoid-ovate, upper leaves narrow and long-acuminate, mucronulate, cuneate, coarsely and irregularly dentate, rarely subentire or erose-dentate; teeth acute and ± incurved. Inflorescences terminal and axillary (leafy) with loosely branched cymes. Perianth segments slightly keeled with a distinct swelling below the apex. Fruit 1.3–1.4 mm, pericarp tightly adjoining the seed, papillate. Seed with prominent keel and surface densely covered with small pits (Fig. 13A, B).

Habitat. Disturbed places; up to 2000 m a.s.l. Reported as a common species in the foothills of Chamba District, Himachal Pradesh (Singh and Sharma 2006).

Phenology. Flowering and fruiting: December-April (in the plains), March-September in the foothills.

Distribution. See Fig. 14.

Specimens examined. INDIA: Jammu & Kashmir: [without locality and date]

Jacquemont s.n. (P04993274); Udhampur, 3 Apr 1987, A. Swami 1089 (BSD);

Himachal Pradesh: Bilaspur Distr., [without date] P. Lai 78966 (BSD); [Simla Distr.] Rampur, 14 Jun 1962, N.C. Nair 22677 (BSD); **Uttarakhand:** Dehradun, 23 May 1972, H. Naithani 3510 (DD); Garhwal Distr., Jogiyna vill., 19 Feb 1979, A.K.

Goel 64713 (BSD); Tehri Garhwal Distr., Chham vill., 10 Apr 1993, B.P. Uniyal 79275 (BSD);

NEPAL: Midwestern: Rapti Zone: [Rolpa Distr.] Phalabang, 4500 ft a.s.l., 24 Mar 1952, O. Polunin, W.R. Sykes & L.H.J. Williams 654 (BM); observed by Sukhorukov in Kathmandu valley and near Bidur village (Bagmati Zone).

General distribution. Widely distributed in tropics and subtropics in all parts of the world. Origin unknown, but Sukhorukov (2014) proposed that it may be Eastern Africa and Arabia, where the morphologically similar *C. fasciculosum* (Aellen) Mosyakin occurs. *Chenopodiastrum murale* is rather common in the plains of India, but there are limited collections from the Himalayan foothills. The species was not observed by AS in Dehradun (Uttarakhand, India) and surroundings in February 2018.

2. *Chenopodiastrum badachschanicum* (Tzvelev) S.Fuentes, Uotila & Borsch, Willdenowia 42(1): 14 (2012)

≡*Chenopodium badachschanicum* Tzvelev, Bot. Mater. Gerb. Bot. Inst. Komarova Acad. Nauk SSSR 20: 434 (1960).

Holotype. TAJIKISTAN, Gorno-Badakhshan Autonomous province, West Pamir, in declivitate lapidosa paulo ruderata in valle fl. Murgab 3–4 km infra ostium fl. Pschart occidentalis, 3300 m alt., 19 June 1958, N.N. Tzvelev 220 (LE, currently on loan in H!).

Taxonomic notes. The “true” *Chenopodiastrum hybridum* reported for some territories (e.g. Chowdhery 1984, Zhu et al. 2003) is not present in Himalaya and Tibet. Additionally, we are uncertain that *C. badachschanicum* described from the Pamir Mountains (Tzvelev 1960) is the correct name for our populations. As recently recognised (Sukhorukov in prep.), the seed surface plays a significant role in the diagnostics of many species of the genus. The type material of *C. badachschanicum* bears small plants (up to 25 cm) with acutely lobed leaves but without ripe seeds. The similar individuals at the fruiting stage were collected in East Kazakhstan, Kyrgyzstan and Tajikistan and their fruits have adherent pericarp and clearly pitted seeds (like those of *C. hybridum*). The plants growing in Himalaya and Tibet are quite uniform in their morphological characters and possess the fruit with loose pericarp and rugulose seed surface. *C. badachschanicum* complex needs further investigations.

Description (based on the specimens growing in our area): Annual up to 100 cm, almost glabrous or only slightly mealy in the upper part. Leaf axils with numerous fertile or sterile brachyblasts. Leaves long-petiolate, continuously shortening upwards; petioles 3.0–10.0 cm; blades 4.0–10.0 cm long, triangular-hastate, entire or with 1–2 unequal lateral lobes in lower part of the leaves, apex attenuate (similar to the leaves of *Atriplex micrantha* C.A.Mey.). Inflorescence leafy or bracteose, consisting of short lat-

eral branches with scattered yellow glands. Perianth segments halfway connate, slightly keeled in the upper part or smooth; margins in the upper part of the segments covered with bladder hairs intermixed with scattered simple hairs. Fruit 1.3–1.8 mm (usually 1.4–1.7 mm) long, 0.9–1.1 mm thick, pericarp brownish, easily ruptured at maturity, slightly alveolate or smooth in dry fruits (with tiny papillae in fresh or soaked fruits). Seed depressed globular, black, keeled, shiny, rugulose, with sinuous surface as well as scattered indistinct longitudinal striae with shallow pits (Fig. 13C, D).

Habitat. Rocks and screes, meadows; margins of spruce and pine forests; 2000–4400 m a.s.l. The collectors also indicate that the species often grows on mossy substrates.

Phenology. Flowering: July–September; fruiting: August–October.

Distribution. See Fig. 14.

NEPAL: Midwestern: Karnali Zone: [Mugu Distr.] Purana Mugu, Mugu Khola, 13000 ft a.s.l., 23 Aug 1952, O. Polunin, W.R. Sykes & L.H.J. Williams 3010 (LE); **Rapti Zone:** [Rukum Distr., nr Ranmamaikot] Seng Khola, 13000 ft a.s.l., 2 Oct 1954, J. Stainton, W.R. Sykes & L.H.J. Williams 4674 (LE); reported for the Mustang District (Yonekura 2008).

General distribution. Himalaya and Tibet: in Nepal, parts of India (Jammu and Kashmir and Uttarakhand), China (Qinghai, Sichuan, Xinjiang, Xizang and Yunnan) and Pakistan (Swat and Quetta). Also present in South Siberia (Altai Mountains).

3. *Oxybasis* Kar. & Kir., Bull. Soc. Imp. Nat. Moscou [14]: 738 (1841)

Type: *Oxybasis minutiflora* Kar. & Kir., Bull. Soc. Imp. Nat. Moscou [14]: 739 (1841)
[= *O. chenopodioides* (L.) S.Fuentes, Uotila & Borsch, Willdenowia 42(1): 15 (2012)].

Description. Annuals, branched from the base or with a single stem, prostrate or erect, glabrous or covered with bladder hairs. Leaves alternate, entire to lobate, rhombic, triangular or oblong, sometimes lanceolate, green from both sides or whitish abaxially. Inflorescence racemiform with lateral branches mostly appressed to the stem; flowers arranged in dense glomerules. Perianth of 3–5 free or diversely connate, hyaline or greenish segments (both perianth forms are present in some species), keeled or not. Flowers bisexual or sometimes female (lateral flowers). Stamens 2–5. Styloodia 2. Pericarp thin, smooth, mamillate or rarely papillate. Seeds usually small (up to 1.2 mm in diameter), red or black. Embryo horizontal or vertical and both embryo positions may be present in one individual (spatial heterospermy). Structural (latent) heterospermy expressed in the varying thickness of the seed coat is common in almost all representatives; outer cell wall of the testa cells with stalactites.

Twelve to fourteen species in the temperate and mountainous parts of Eurasia, Africa and the Americas. One species in Himalaya and Tibet.

1. *Oxybasis glauca* (L.) S.Fuentes, Uotila & Borsch, Willdenowia 42(1): 15 (2012)

≡ *Chenopodium glaucum* L., Sp. Pl.: 220 (1753). **Lectotype** (designated by Uotila 1993): Herb. Linn. 313.17 (LINN! image of the lectotype available at <http://linnean-online.org/3142/>).

≡ *Botrys glauca* (L.) Nieuwl., Am. Midl. Naturalist 3: 275 (1914).

Description. Annual up to 70 cm, branched from the base, sometimes forming cushion-like habit at high elevations; stem often prostrate to ascending, rarely straight. Leaves up to 6 × 2 cm, petiolate, cuneate at base, oblong or lanceolate, dentate or lobate with 2–5 lobes, rarely entire, green adaxially, grey or whitish below. Inflorescence leafy, loose. Perianth segments 3 to 5, almost free with hyaline margins, keeled along

Figure 15. Distribution map of *Oxybasis glauca*.

midrib, opened at fruiting stage. Fruit 0.65–0.8 mm in diameter, pericarp smooth, whitish, often ruptured. Seed reddish, without keel; embryo in both vertical and horizontal positions (spatial heterospermy), structural (latent) heterospermy expressed in different thickness of seed-coat testa.

Habitat. Rocks, streams or other wet (often sandy) places; 2800–4600 m a.s.l.

Phenology. Flowering: July–September; fruiting: August–October.

Distribution. See Fig. 15.

Specimens examined. CHINA: Xizang: Ngari Prefecture: Rutog (Ritu) County, west of Lake Bangong (Pangong Tso), 4200 m a.s.l., 11 Jul 1974, *Biological Institute Tibet Expedition Team 3604* (HNWP40756); Rutog (Ritu) County, Lake Bangong (Pangong Tso), 4240 m a.s.l., 4 Sep 1976, *Qinghai-Tibet Team Vegetation Group 13673* (PE00511499); Xigazé Prefecture: Tingri, Jul 1921, A. Wollaston 265 & 266 (K); Namling (Nanmulin) County, Gangba, 4000 m a.s.l., 3 Aug 1972, *Tibet Chinese Herbal Medicine Survey Team 983* (PE00511498, HNWP29013); Gyangzê (Jiangzi) County, 3760 m a.s.l., 5 Sep 1974, *Qinghai-Tibet Team 74-2068* (KUN0587252); Lhasa City: Lhasa, 15 Apr 1960, Fu & Zhang 0046 (PE00511501); Shannan Prefecture: Zetang, Changzhu, 3550 m a.s.l., 27 May 1986, K.Y. Lang et al. 1470 (PE00511496); Nyingchi Prefecture: [Nyingchi (Linzhi) County] Tsangpo, nr Lamdo, 29°23'N, 94°22'E, 9800 ft a.s.l., 30 May 1938, F. Ludlow et al. 4574 (BM, E);

INDIA: Jammu & Kashmir: [without locality and date] Jacquemont 1151 (P04993386; P04993387); Leh, 1 Aug 1976, B.M. Wadhwa 59401 (BSD); Tirit vill., 3200 m a.s.l., 18 Aug 1976, B.M. (PRA); Ladakh, Indus valley, Sham (W), Angshang to Konzke La, 4310–4370 m a.s.l., 21 Sep 2006, L. Klimes 7308 (PRA).

The specimens collected in Himachal Pradesh and Uttarakhand and identified as “*Chenopodium glaucum*” belong to other taxa, mostly *Atriplex pallida* (Moq.) Sukhor.

NEPAL: Western: Dhaulagiri Zone: Mustang Distr., Chuksang (2970 m a.s.l.)–Tetang (3000 m a.s.l.)–Gnyu Pass (4100 m a.s.l.), 28°55'N–28°51'N, 83°49'E, 13 Jul 2000, Y. Iokawa et al. 20020169 (E00435483).

General distribution. Eurasia (mostly temperate regions), North America, North Africa. In Himalaya and Tibet, the species is found at high altitudes (2800–4600 m a.s.l.) and the plants hardly reach 30 cm in length. Its frequency is not known, but it seems to be rare in our area.

4. *Atriplex* L., Sp. Pl.: 979 (1753).

Lectotype (designated by McNeill et al. 1983): *Atriplex hortensis* L.

Description. Annual herbs, subshrubs or shrubs, monoecious or dioecious, covered with bladder hairs having short basal cell and globular terminal cell; occasionally, other hair types (simple bristle-like or curved hairs) can be detected under higher magnification. Leaves alternate or opposite, simple, flat, petiolate. Inflorescence leafy or not, consisting of few or numerous flowers that are usually unisexual. The male and bisexual flowers are enclosed by (3–4)5 green perianth segments that remain unchanged at fruiting in bisexual flowers; female flowers enclosed by two accrescent perianth segments [valves] (often called ‘bracteoles’ or bract-like cover) that are free or connate to varying degrees. Seeds have a vertical embryo, some seeds rarely with horizontally orientated embryo. Often (in annual species) heterosperry is present (seed coat black and brown/red).

The largest genus amongst the Chenopodiaceae (~260 species).

Key to the species

- 1 Leaves opposite to alternate, ovoid or triangular, usually reddish and sparsely covered with bladder hairs (except young leaves, which are densely covered with bladder hairs). Plant bears three types of flowers (male and bisexual flowers surrounded by perianth of (4)5 normal segments and female flowers supported only by a bract-like cover formed of two accrescent valves that are only basally connate); seeds heteromorphic (black and brown) **4. *A. hortensis***
- Leaves alternate, broadly ovoid, rhombic to triangular, always farinose (at least below) or often additionally covered with brown bladder hairs; no bisexual flowers present (male flowers surrounded by perianth of (4)5 normal segments and female flowers supported by a bract-like cover); segments of bract-like cover at least half connate; seeds red and brown **2**

- 2 Inflorescence aphyllous or bracteate; bract-like cover of female flowers smooth or with 2(3) small outgrowths..... **2. *A. pallida***
 – Inflorescence leafy (almost) to the top..... **3**
- 3 Plant forming tumble-weed habit; stem erect with spreading branches; leaves rhombic or ovate; bract-like cover of female flowers either smooth or with thorn-like outgrowths (on the same plant) **1. *A. centralasiatica***
 – Plant not forming tumble-weed habit; leaves oblong; bract-like cover smooth or with 1–2 small outgrowths **3. *A. pamirica***

1. *Atriplex centralasiatica* Iljin, Act. Inst. Bot. Ac. Sci. USSR, ser. 1, 2: 124 (1936)

Holotype. [KAZAKHSTAN] Lac. Balchasch, prope Aczie [Balkhash Lake, near Acschi], 19 Sep 1930, E. Czerniakowska 819 (LE!).

Taxonomic notes. Some specimens collected in China (e.g. Xinjiang, Xizang and Qinghai), East Kazakhstan and Kyrgyzstan are characterised by the presence of long-stalked bract-like cover of female flowers and such plants were described as *A. megalotheca* Popov and *A. tianschanica* Pratov. We believe that these two species are indeed varieties of *A. centralasiatica*. In the preliminary, recently constructed ITS tree (Sukhorukov et al. in prep.), the specimens of *A. centralasiatica* and *A. megalotheca* (*A. tianschanica* was not included in the analysis) are intermixed within one subclade (as a part of the C₄-*Atriplex* clade). A closely related *Atriplex sibirica* possesses bract-like cover with warty or spiny outgrowths, whereas *A. centralasiatica* is distinguished by having two forms of the valves, with and without outgrowths (smooth on dorsal side). The results of the first molecular phylogeny of the genus support the existence of two morphologically similar species, *A. sibirica* and *A. centralasiatica* (Kadereit et al. 2010). The distribution area of *A. sibirica* mostly covers the northern and middle parts of Central Asia and no specimens were seen from Tibet and Himalaya. For this reason, *A. centralasiatica* is still considered to be in its own specific rank.

Description. Annual up to 50 cm, basally branched and forming a tumble-weed habit at the fruiting stage. Leaves triangular or rhombic-triangular, rarely ovate, mostly entire. Inflorescence leafy to the top. Female flowers in axillary clusters and intermixed with male flowers, forming terminal inflorescences. Bract-like cover enclosing the female flowers sessile or pedunculate (peduncles up to 2 cm), rhombic with concrescent (from 1/2 to 2/3) valves 5.0–10.0(15.0) mm long, sclerified and slightly inflated, entire or dentate, either without abaxial outgrowths or with acute outgrowths. Seeds heteromorphic: red seeds convex, 1.5–2.0(2.5) mm in diameter, brown seeds 2.0–2.5(3.0) mm, flattened.

Habitat. Screees, roadsides at altitudes of 3500–4800 m a.s.l. (in Himalaya and Tibet). Widespread in Tibet and in some parts of Ladakh (India).

Phenology. Flowering: July–September; fruiting: September–October.

Distribution. See Fig. 16.

Bartanga [river bank of Bartanga river], in decliviis lapidosis [rocky slopes], 20 Aug 1897, S. Korshinsky 4692 (LE! isolectotype LE!).

Description. Annual up to 70 cm, basally branched with ascending stems. Leaves triangular, oblong or rhombic-triangular, entire or dentate, sometimes with two marginal lobes; upper leaves lanceolate. Inflorescence leafy in lower part. Female flowers in axillary clusters and intermixed with male flowers forming terminal inflorescences. Bract-like cover enclosing the female flowers sessile or shortly pedunculate (peduncles up to 3.0 mm), ovate, rhombic or triangular, 1.2–5.0(7.0) mm long, sclerified but not or slightly inflated, entire or dentate, usually without outgrowths on the back. Seeds heteromorphic: red seeds convex, 0.7–1.2 mm in diameter, brown seeds 1.2–1.8 mm, flattened.

Habitat. Scree, sands and ruderal sites; 2600–4800 m a.s.l.

Phenology. Flowering: August-September; fruiting: September-October.

Distribution. See Fig. 16.

Janardhanan 47780 & 47781 (BSD); Spiti valley, Kibber, 4250 m a.s.l., 2 Aug 1972, U.C. Bhattacharyya 49260 (BSD); Spiti valley, Tabo vill., 19 Aug 1994, S.K. Musti & S. Singh 88480 (BSD); Kinnaur Distr., Skiba vill., 9 Oct 1991, K.P. Janardhanan 46553 (BSD); Spiti Distr., Pin Valley National Park, 27 Aug 2002, K.C. Sekar 100735 (BSD); **Uttarakhand:** Chamoli Distr., Malari vill., 20 Aug 1979, B. Nailhani 56011 (BSD).

General distribution. Tajikistan, Afghanistan, NE Pakistan, N India. Most likely present in W Xizang (China). Common in Ladakh, many parts of Himachal Pradesh and Uttarakhand (Chamoli Distr.).

3. *Atriplex pamirica* Iljin, Acta Inst. Bot. Ac. Sc. USSR, ser. 1, 2: 124 (1936)

Atriplex pamirica Iljin, Acta Inst. Bot. Ac. Sc. USSR, ser. 1, 2: 124 (1936). **Holotype:** [TAJIKISTAN] Khargosh, in ripa lac. Kara-kul [bank of Kara-kul Lake], 30 Jul 1878, Yu. Ashurbayev s.n. (LE!).

≡*Atriplex tatarica* var. *pamirica* (Iljin) G.L.Chu in Kung & Tsien, Fl. Reipubl. Pop. Sin. 25(2): 46 (1979).

Taxonomic notes. *Atriplex pamirica* is a morphologically highly recognisable species (Sukhorukov 2006). The varietal rank *Atriplex tatarica* var. *pamirica*, proposed by Chu in Kung and Tsien (1979), cannot be accepted. *Atriplex tatarica* is a taller plant with an aphyllous or bracteose inflorescence. The results of molecular phylogeny have confirmed the specific rank of *A. pamirica* (Kadereit et al. 2010).

Description. Annual up to 30(50) cm, branched at the base with ascending stems but not forming tumble-weed habit at the fruiting stage. Stems and leaves covered with white and brown bladder hairs. Leaves grey on both sides, oblong or spatulate, entire or crisp. Inflorescence leafy. Bract-like cover enclosing the female flowers 3.0–7.0 mm long, rhombic, entire or dentate with concrescent (up to 1/3–1/2) valves, valves sessile or pedicellate (pedicels up to 3 mm), sclerified and inflated in the lower part, abaxial surface smooth or with two small outgrowths. Seeds heteromorphic: red seeds convex, 1.0–1.7 mm, brown seeds flattened, 1.2–1.8 mm.

Habitat. Scree or roadsides at altitudes of 3500–5300 m a.s.l.

Phenology. Flowering: July–September; fruiting: September–October.

Distribution. See Fig. 17.

Specimens examined. INDIA: Jammu & Kashmir: Ladakh, Rupshu Region, Samad Rakchan, Pongunagu, 33°22'N, 77°57'E, 4670 m a.s.l., 29 Aug 1998, *L. Klimeš* 254 (PRA); Ladakh, Rupshu Region, Tso Moriri, 5170–5200 m a.s.l., 12 Aug 2001, *L. Klimeš* 1335 (PRA); Ladakh, Pangong Region, Spangmik, 4300–4320 m a.s.l., 9 Sep 2002, *L. Klimeš* 2678 (PRA).

General distribution. Tajikistan, Afghanistan, NE Pakistan and N India. Most likely, present in NW Xizang (China).

4. *Atriplex hortensis* L., Sp. Pl.: 1053 (1753)

Lectotype (designated by McNeill et al. 1983): Hort. Sicc. Cliff. (BM000647538! image of the lectotype available at <http://www.nhm.ac.uk/resources/research-curation/projects/clifford-herbarium/limages/BM000647538.JPG>).

- =*A. heterantha* Wight, Icon. Pl. Ind. Orient. 5: tab. 1787 (1852). **Holotype:** [INDIA] Coimbatore, Nov 1849 [Wight] 2481 (K000898565!).
=*A. microtheca* Moq. in DC., Prodr. 13(2): 91 (1849) nom. illegit., non Fries 1835.
Type: not selected.

Description. Annual up to 150 cm, erect, usually branched. Leaf petioles 1.5–4.0 cm, blades 4.0–15.0(22.0) × 3.5–7.0(8.0–20.0) cm, triangular-hastate or ovoid, entire or dentate, basally slightly cordate or rounded, apically obtuse, green or reddish, glabrous or with scattered bladder hairs abaxially. Inflorescence mostly basally leafy, spike-like. As a rule, three kinds of flowers are present: (i) male flowers surrounded by a perianth with (4)5 segments, (ii) bisexual flowers surrounded by a perianth with (4)5 segments (sometimes not observed in the Indian specimens) and (iii) female flowers supported only by two accrescent, basally connate perianth valves forming a bract-like cover up to 12.0(15.0–20.0) mm in diameter, valves sessile or sometimes tapered into a peduncle up to 5 mm long (seen on Indian material). Seeds heteromorphic (three seed types present on one individual). Black seeds (1.6–1.8 mm in diameter) are formed in second (ii) and third (iii) flower types while the brownish ones (2.0–3.5 mm) are usually yielded by female (iii) flowers.

Habitat. Disturbed places (cultivated in vegetable gardens or as a weed); 2500–3600 m a.s.l. (in our area).

Phenology. Flowering: July-September; fruiting: September-October.

Distribution. See Fig. 17.

Specimens examined. INDIA: Jammu & Kashmir: Ladakh, Leh, 1856, *Schlagintweit* [several sheets s.n., nrs 9 & 10] (BM, G, P04930288); Ladakh, Up-schi to Leh, Aug 1856, *Schlagintweit* 1290 (E); Ladakh, Chushul, 5500 m a.s.l., 24 Sep 1975, M.V. NEPAL: “Napalia” [without precise location and year] 1821, *R. Wight* 9089 (K, LE).

General distribution. Eurasia (seems to be native in southern Europe and Turkey only); cultivated and sometimes well-established in Northern Himalaya, North and South America and Australia.

Excluded species

All records of the species listed below are erroneous (see for more Sukhorukov 2006) and belong to different species listed above or even to some *Chenopodium*.

Atriplex laciniata sensu auct. non L. It is distributed on the shores of West, South-West and Central Europe and eastern part of North America.

A. rosea auct. non L. It is distributed in Europe, North Africa and Turkey; as alien in North and South America.

A. nitens sensu Paul (2012) non Schkuhr [=*A. sagittata* Borkh.]. It is known from Europe and temperate Asia (Caucasus, Siberia).

A. crassifolia sensu Dhar and Kachroo (1983), Sekar and Srivastava (2009), Paul (2012) non C.A.Mey. An endemic to Eastern Kazakhstan and West Xinjiang, China (Sukhorukov 2006, Nobis et al. 2017).

5. *Microgynoecium* Hook.f. in *Bentham & Hook.f., Gen. Pl. 3(1): 56 (1880)*

Microgynoecium Hook.f. (1880). Type: *Microgynoecium tibeticum* Hook.f.

Description. Monoecious annuals up to 20 cm with scattered, long-stalked bladder hairs; stems branched, prostrate or ascending; at elevations above 5000 m plants

Figure 17. Distribution map of *Atriplex pamirica* (circles), *A. hortensis* (stars) and *Microgynoecium tibeticum* (triangles).

are often cushion-like. Leaves fleshy or not, petiolate (petiole up to 1.5–2.0 cm), green, leaf blades up to 1.5 cm, decreasing in size upwards, entire, rhombic, ovate or oblong, mostly entire or sometimes with small lateral lobes. Male flowers inconspicuous with (4)5 hyaline perianth segments and 2–4 stamens with large (ca. 2.0 mm) protruding filaments in anthesis, anthers ~0.5 mm; female flowers hidden in bract (each bract usually covers 3 female flowers) without a conspicuous perianth. Fruits and seeds dimorphic. The fruits of the first type reddish-brown, 0.9–1.0 mm long, 0.4–0.5 mm thick, ear-like pericarp appendages in the upper part of the fruit up to 0.1 mm and much smaller in the lower part; pericarp one-layered, some cells papillate; seed testa 10–12 µm thick, undulate, outer cell walls with stalactites. The fruits of the second type dark, 1.0–1.5 mm long, 0.75–0.80 mm thick (visibly swollen) with ear-like pericarp outgrowths up to 0.1 mm expressed throughout; pericarp one-layered with papillate cells, 12–15 µm; seed coat testa 20–25 µm thick. Seed coat tegmen of both seed types minute; embryo vertical, annular; perisperm present. The fruit anatomy is similar to that of *Archiatriplex* Chu (Kadereit et al. 2010), especially in the presence of pericarp outgrowths over the fruit surface (Sukhorukov 2014).

One species in Himalaya, Tibet, Pamir and Tian Shan.

1. *Microgynoecium tibeticum* Hook.f., Fl. Brit. India 5(13): 9 (1890)

Lectotype (designated by Sukhorukov and Kushunina 2014): [INDIA, Uttarakhand State, Kumaon Division] Topedunga, 15000 ft a.s.l., S. Strachey & J.E. Winterbottom 1 (K000898740! image of the lectotype available at <http://apps.kew.org/herbcat/getImage.do?imageBarcode=K000898740>, isolectotypes K! P04921830! P04930937!).

Description. See the genus description. *Microgynoecium tibeticum* is often confused with *Chenopodium pamiricum*; both species are present in North Himalaya at high altitudes. In the early blooming stage, *M. tibeticum* differs by having unisexual flowers and long (2.0 mm) filaments of stamens protruding from the perianth (*Chenopodium pamiricum* has bisexual flowers and shorter filaments). The fruit and seed characters greatly differ between the genera.

Habitat. Scree, grassy slopes or ruderal sites; 3500–5500 m a.s.l.

Phenology. Flowering: August–October; fruiting: September–November.

Distribution. See Fig. 17.

Specimens examined. Description. Annual or perennial herbs, glabrous or covered with bladder hairs (scattered glandular hairs may be present). Leaves long-petiolate with triangular, hastate or rhombic blades; basal leaves often in a rosette. Inflorescences leafy or aphyllous in the upper part. Flowers in dense glomerules, bisexual or sometimes unisexual. Perianth of 1–5 free or insignificantly concrescent segments or perianth reduced, green, but sometimes fleshy and red or indurated in the fruiting stage. Stamens 1–5, usually equalling the perianth

segments. Stigmas 2–3. Fruits with 1–2(3)-layered, smooth or mamillate pericarp, usually tightly adjoining the seed coat. Seed round or ovoid, red or reddish-black, without keel or with 2 blunt keels. Seed surface smooth or alveolate; testa cells without stalactites, sometimes with hair-like outgrowths. Seed embryo horizontally or vertically orientated or sometimes both embryo positions present on an individual (spatial heterospermy).

Approximately 14 species worldwide.

1. *Blitum virgatum* L., Sp. Pl.: 4 (1753)

Blitum virgatum L., Sp. Pl.: 4 (1753). **Lectotype** (designated by Jafri and Rateeb 1978): Herb. Linn. 14.2 (LINN! image available at <http://linnean-online.org/60/>).
 =*Morocarpus foliosus* Moench, Methodus: 342 (1794). **Type:** not designated.
 ≡*Chenopodium foliosum* (Moench) Asch., Fl. Brandenburg: 572 (1864).

Description. Annual or short-lived perennial up to 60 cm tall, glabrous or covered with scattered glandular hairs in the upper part. Basal leaves numerous, up to 25 cm long, caudine leaves up to 20 cm, long-petiolate with triangular blades, truncate or slightly cuneate at base, margins erose-dentate or lobate. Inflorescence leafy to the apex; bracts dentate to lobate. Flowers in dense clusters up to 8 mm in diameter. Perianth segments 3–5, basally concrecent, green and membranous at anthesis but usually turning red and fleshy at the fruiting stage (sometimes remaining green). Pericarp adhering to the seed coat, hyaline, consisting of 1(2) very thin layers. Seeds ovoid, 1.0–1.2 × 0.7 mm, dark red, with a groove and two blunt keels.

Habitat. Scree and sandy valleys, also cultivated (fruit conglomerations or “berries” are edible or used as a rouge); 2600–4400 m a.s.l.

Phenology. Flowering: June-August; fruiting: July-September.

Distribution. See Fig. 18.

General distribution. Temperate Eurasia, native to the mountains of Europe, the Caucasus, South Siberia, Central Asia and Himalaya.

Tribe Dysphanieae Pax in Engler & Prantl, Nat. Pflanzenfam. 3, I b: 92 (1889)

7. *Dysphania* Brown, Fl. Nov. Holland.: 411 (1810)

Dysphania littoralis R.Br., Prodr. Fl. Nov. Holland. 412 (1810) (**Type**).

=*Roubieva* Moq., Ann. Sci. Nat. Bot., ser. 2(1): 292 (1834); **Type:** *Roubieva multifida* (L.) Moq. (≡*Dysphania multifida* (L.) Mosyakin & Clemants).

=*Ambrina* Spach, Hist. Nat. Vég. 5: 295 (1836); **Lectotype** (Simón 1996): *Ambrina ambrosioides* (L.) Spach (≡*Dysphania ambrosioides* (L.) Mosyakin & Clemants).

=*Botrydium* Spach, Hist. Nat. Vég. 5: 298 (1836) nom. illegit., non Wallroth (1815).

Lectotype (Scott 1978): *Botrydium aromaticum* Spach (=*Dysphania botrys* (L.) Mosyakin & Clemants);

=*Neobotrydium* Moldenke, Amer. Midl. Naturalist 35: 330 (1946). **Type:** *Neobotrydium botrys* (L.) Moldenke, Amer. Midl. Naturalist 35: 330 (1946) (=*Dysphania botrys* (L.) Mosyakin & Clemants);

Description. Aromatic annuals or, rarely, perennial herbs and small subshrubs covered with glandular hairs, subsessile yellow or orange glands and simple white hairs. Leaves alternate, entire, lobe or pinnatisect. Inflorescence lax or dense, leafy or not, consisting of cymes that are often reduced to one flower only. Perianth segments 2–5, free or variously connate, the midrib usually with keel. Stamens 1–5. Styles 2, free or basally connate. Fruit subglobose or rarely flattened, 0.3–1.5 mm, its surface reticulate or papillate, rarely smooth, dark coloured but often with whitish longitudinal stripes. Pericarp adjoining the seed coat, rarely bursting, hyaline, consisting of 1–2 very thin layers. Seed reddish or reddish-black, sometimes brown, its testa (outer seed coat layer) lacking vertical tannin-like deposits called “stalactites” in cross-section. Embryo horizontal or vertical, sometimes in both positions within one plant (spatial heterospermy).

More than 50 species worldwide, mostly in the tropics and subtropics. According to the first comprehensive molecular phylogeny (Kadereit et al. in prep.), the genus *Dysphania* is monophyletic and there is no reason to accept the genera *Neobotrydium* or *Ambrina* as was recently proposed (Zhang and Zhu 2016, Zhu and Sanderson 2017). All native species are closely related and belong to a large clade consisting of Eurasian and African representatives. The mountainous areas of Himalaya and Tibet are now considered one of the four centres of *Dysphania* diversity, together with Australia, South America and East Tropical Africa (Sukhorukov and Kushunina 2014, Sukhorukov et al. 2016a). The evident structural fruit and seed dimorphism in *Dysphania* (*D. tibetica*) is stated here for the first time.

Key to species

- | | | |
|---|--|---|
| 1 | Annuals or short-leaved perennials up to 1.5(2.0) m tall, growing mostly at elevations up to 2300 m; inflorescence dense, spike-like; perianth half connate or nearly so, enclosing the fruit completely and falling off with the fruit; pericarp covered with glandular hairs in its upper part1. <i>D. ambrosioides</i> | |
| - | Annuals, mostly much smaller, growing at higher elevations; inflorescence loose, thyrsoid; perianth almost free or its segments concrecent up to 1/3 of their length, persistent at fruiting; pericarp with short papillae (visible at high magnification) | 2 |
| 2 | Inflorescence branches often terminate with short flattened aristae; subsessile glands scattered; fruits dimorphic (subspherical and ovoid).....7. <i>D. tibetica</i> | |
| - | Inflorescence branches without aristae; glands always present and abundant; fruits (sub)spherical | 3 |

- 3 Leaves entire, sinuate or lobate; seed embryo usually vertical....**2. *D. himalaica***
 – Leaves lobate, pinnatifid or pinnatisect, very rarely almost entire and crisp; seed embryo horizontal **4**
- 4 Leaf petioles short (up to 1.0 cm); inflorescence spike-like (with reduced or short lateral branches); perianth with numerous large simple stout hairs up to 0.3 mm, the bases of which can be concrescent, resulting in 2–3-furcate tips; fruits 0.5–0.6 mm in diameter **6. *D. geoffreyi***
 – Leaf petioles (at least of basal leaves) longer than 0.5 cm; inflorescence not spike-like, with well-expressed lateral branches; stout simple hairs on the perianth (if present) usually not concrescent at the base; fruits 0.6–0.8 mm **5**
- 5 Perianth with simple and (stalked) glandular hairs **6**
 – Perianth with simple hairs and subsessile glands; glandular hairs on perianth absent or very scattered (not visible at lower magnification) **7**
- 6 Plant robust, up to 100(120) cm, stem highly branched, densely covered (especially in the upper part) with both simple and glandular hairs up to 1 mm long **8. *D. neglecta***
 – Plants up to 50 cm, stem mostly branched in the lower part with scattered hairs up to 0.3 mm long **5. *D. botrys***
- 7(5) Simple hairs on perianth segments scattered (mostly localised near the segment tips) or even absent; partial inflorescences recurved, umbel-like **4. *D. kitiae***
 – Simple hairs on perianth segments abundant **8**
- 8 Leaves pinnatisect; glands yellow and/or orange **3. *D. bhutanica***
 – Leaves pinnatifid or lobate; plant with yellow glands **9. *D. nepalensis***

≡*Neobotrydium ambrosioides* (L.) M.L.Zhang & G.L.Chu [Zhu], Pl. Diversity 38(6): 327 (2016).

Taxonomic notes. In the species circumscription, we follow the opinion of Mosyakin and Clemants (2002) and Iamonico (2011) and maintain separation from *D. anthemintica* (L.) Mosyakin & Clemants.

Figure 19. *Dysphania ambrosioides*: **A** general view **B** close-up of the inflorescence branch. Photographs by A. Sukhorukov (Dehradun, Uttarakhand, India, February 2018).

Description. Annual or short-lived perennial up to 1.5(2.0) m, very aromatic, covered (at least the young parts of the plant) with curved simple hairs, yellow (subsessile) glands and glandular hairs with a prominent stalk. Leaves long-petiolate, 5.0–16.0 × 1.0–4.0 cm, elliptic-oblong or lanceolate, dentate or sinuate; upper leaves often entire. Inflorescence usually highly branched, spike-like, bracteate or aphyllous in the upper part. Flowers sessile. Perianth segments (4)5, green, ca. 1.0 mm long, (nearly) half concrescent, concave near the apex, completely enclosing the fruit (Fig. 20A). Pericarp thin, hyaline, tightly adjoining the seed coat but separating from it when rubbed, in its upper part covered with glandular hairs (up to 0.12 mm long) with a large terminal cell (Fig. 20B). Seed dark red or almost black, 0.7 × 0.5–0.6 mm, not keeled. Embryo horizontal, rarely oblique or vertical.

Habitat. Disturbed places and riversides, gravelly substrates; 0–2300 m a.s.l.

Phenology. Flowers and fruits year-round. Fruits develop only at elevations up to 2300 m. At higher elevations, the plants, even if occasionally present, do not produce flowers and fruits (Sukhorukov and Kushunina 2014).

Distribution. See Fig. 21.

Klimeš 6175 (PRA! isotypes (5) PRA! H1758789!).

=*Neobotrydium longii* [*langii*] G.L.Zhu in Zhu & Sanderson, Gen. & New Evol. System World Chenopod.: 334 (2017), syn. nov. **Holotype.** CHINA, Tibet [Xizang], Mami division, Gaize Xian (Gérzê County), Chacuo, 4500 m a.s.l., 8 Sep 1976, K.-Y. Long [*Lang*] 10153 (PE00511004!).

Taxonomic notes. During the last visit of the first author (AS) to the herbarium of the Institute of Botany of the Chinese Academy of Sciences (PE) in early 2017, the type of *Neobotrydium longii* had not yet been selected and the specimen without a new determination was kept with all other *Dysphania* in a folder under the old name “*Chenopodium foetidum*”. The synonymisation of *N. longii* [*langii*, named after K.-Y. Lang] with *D. himalaica* is made here for the first time based on the re-identification of specimen PE00511004 by AS.

Description. Annual up to 15(20) cm, mostly branched from the base. Leaves appressed to the stem, short-petiolate, up to 4.0×1.0 cm, narrowly oblong or lanceolate, entire, sinuous or slightly lobate, green, with scattered simple hairs and subsessile yellow glands. Inflorescence leafy in the lower part, covered with short, semi-appressed white simple hairs (up to 0.4 mm long) and scattered subsessile yellow glands. Perianth segments (4)5, $0.9\text{--}1.2 \times 0.25\text{--}0.40$ mm, almost free, somewhat swollen near midrib with a short, white or reddish mucro(s) at the tip, their dorsal part with stout simple

hairs (up to 0.15 mm), often red at the segment tips and scattered glands up to 0.1 mm (Fig. 20C). Pericarp whitish, minutely papillate, separating from the seed (Fig. 20D). Fruit 0.7–0.9 × 0.7 mm, subspherical; seed reddish, keeled; embryo vertical or sometimes horizontal (spatial heterospmy).

Habitat. Gravelly slopes and ruderal sites at elevations of 3000–4900 m a.s.l.

Phenology. Flowering: August–September; fruiting: September–October.

Distribution. See Fig. 21.

General distribution. Himalaya and Tibet (India, Nepal and China). Common in Jammu & Kashmir and many parts of Tibet (L. Klimeš, G. & S. Miehe, pers. comm.); probably rare in Nepal.

3. *Dysphania bhutanica* Sukhor., Willdenowia 42(2): 171 (2012)

Holotype. BHUTAN, Thimphu distr., Lango, near Paro, frequent weed in apple and other crops, 2300 m a.s.l., 29 Jun 1992, C. Parker 7263 (E00051983! image available at <http://data.rbge.org.uk/herb/E00051983>).

Description. Annual up to 100 cm. Stem covered with short simple hairs and subsessile, orange or yellow glands. Leaves pinnatisect, 2.0–9.0 × 1.0–2.5 cm, long-petiolate; their segments oblong or lanceolate, sinuate to lobed, usually densely covered with short simple hairs intermixed with scattered glands. Inflorescence up to 20 cm long, leafy at least in basal and middle parts with scattered curved simple (up to 0.2 mm) hairs and subsessile glands. Perianth segments 5, almost free, 0.7–0.9 × 0.35–0.40 mm; their dorsal part with stout simple hairs (up to 0.08 mm) and orange (rarely yellow) glands (Fig 20E). Fruit 0.6–0.7 × 0.5 mm in diameter, subspherical, pericarp minutely papillate (Fig. 20F). Seed blackish, keeled; embryo horizontal.

Habitat. Grassy hill slopes and disturbed areas; 2200–3800 m a.s.l.

Phenology. Flowering: June–August; fruiting: July–September.

Distribution. See Fig. 22.

Figure 22. Distribution map of *Dysphania bhutanica* (circles) and *D. kitiae* (stars).

NEPAL: Western: Dhaulagiri Zone: [Mustang Distr., Kali Gandaki river valley] Tukuche, 10500 ft a.s.l., 21 Aug 1954, J. Stainton, W.R. Sykes & L.H.J. Williams 7356 (BM). The plant has yellow glands only and identification is based on the pinnatisept leaf shape.

General distribution. E Himalaya and S Tibet.

4. *Dysphania kitiae* Uotila, Willdenowia 43(1): 75 (2013)

Dysphania kitiae Uotila, Willdenowia 43(1): 75 (2013). **Holotype.** CHINA, Gansu [Prov.], Monastery Chorten-tan, on sunny slopes on clay and rich soil, 7000 ft a.s.l., early September 1901, V.F. Ladygin 596 (LE!).

=*Chenopodium aristatum* L. forma *muticum* J.Q.Fu Fl. Loess-Plateaus Sin. 1: 610 (2000), nom. illegit.

=*Neobotrydium corniculatum* G.L.Chu & M.L.Zhang, Pl. Diversity 38(6): 325 (2016), syn. nov. **Holotype:** CHINA, Gansu [Prov.], Diebu Xian, Wangzang, foot of slopes, [date of collection not indicated in the protologue] G.L. Chu 15618 (NWTC, n.v.).

Taxonomic notes. The name *Chenopodium aristatum* L. forma *muticum* (Fu 2000) is published with two holotypes and this is considered an uncorrectable error according to ICN (Turland et al. 2018), art. 40.6. Another name, *Neobotrydium corniculatum*, is synonymised here for the first time based on the following observations: (1) description of *N. corniculatum* and the drawing of the entire plant, especially perianth features, correspond with *Dysphania kitiae*; (2) specimens kept at the PE and WUK herbaria and cited as *Dysphania kitiae* by Sukhorukov and Kushunina (2014) are the same as those listed by Zhang and Zhu (2016) for *Neobotrydium corniculatum*. One of the specimens of *Neobotrydium ornithopodium* G.L. Chu & M.L. Zhang (Zhang and Zhu 2016), cited in the protologue (Hebei prov., leg. Hsia 2448, WUK!), is in fact *Dysphania kitiae* (see citation of the specimens in Sukhorukov and Kushunina (2014)). We have not investigated the holotype of *Neobotrydium ornithopodium*, a species closely related to *Dysphania nepalensis*.

Description. Annual up to 50 cm, strongly aromatic. Leaves 4.0–10.0 × 2.0–4.0 cm, long-petiolate, elliptic-oblong in outline, apex rounded. Inflorescence with indumentum consisting of scattered short simple hairs (up to 0.3 mm long) and subsessile glands. Perianth segments 5, basally connate, 1.0–1.2 × 0.5–0.6 mm; their dorsal part with yellow glands and scattered stout simple hairs (up to 0.1 mm), the latter mostly localised in the upper half of the segments (Fig. 20G). Fruit 0.7–0.9 mm, subspherical. Pericarp with minute conical papillae up to 25 µm (Fig. 20H); seed blackish; embryo horizontal.

Habitat. Grassy slopes and waste areas at altitudes of 2000–3800 m a.s.l.

Phenology. Flowering: July–September; fruiting: August–October.

Distribution. See Fig. 22.

Specimens examined. **CHINA: Xizang: Lhasa City:** W of Lhasa, 3800 m a.s.l., 15 Jun 1974, Mountaineering Scientific Expedition Team 310 (HNWP42358); **Nyingchi Prefecture:** Zhamo (Bomi) County, 2700 m a.s.l., 16 Jul 1965, Zhang & Lang 314 (PE00511015); Zayü (Chayu) County, Cawarong (Chawalong) Distr., 2800 m a.s.l., 28 Sep 1982, Qinghai-Tibet Team 10836 (PE01063458).

General distribution. South-West, Central and North-East China (for more, see Sukhorukov and Kushunina (2014)).

5. *Dysphania botrys* (L.) Mosyakin & Clements, Ukr. Bot. Zhurn. 59(4): 383 (2002)

- ≡*Chenopodium botrys* L., Sp. Pl.: 219 (1753). **Lectotype** (Jafri and Rateeb 1978): Herb. Linn. 313.12 (LINN).
- ≡*Vulvaria botrys* (L.) Bubani, Fl. Pyren. 1: 177 (1897);
- ≡*Botrydium botrys* (L.) Small, Man. S.E. Fl.: 466 (1933);

- =*Botrydium aromaticum* Schap., Hist. Nat. Veg. 5: 299 (1836).

Description. Annual up to 50 cm, mostly branched from the base, green or yellowish-green; stem and leaves densely covered with simple (up to 0.3 mm long) and glandular hairs. Lower leaves long-petiolate, up to 6.0(7.0–10.0) cm, pinnatifid; middle and upper leaves shorter, up to 5.0 cm, sometimes almost entire and crisp, very aromatic. Inflorescence up to 20 cm long with ± dense indumentum consisting of curved simple (up to 0.3 mm) hairs partially intermixed with glandular hairs. Perianth segments 5, free, 0.7–0.8 × 0.5 mm; their dorsal part with glandular hairs (up to 0.125 mm long) having scaphoid terminal cell and with scattered stout simple hairs up to 0.075 mm (Fig. 23A). Fruit 0.6–0.8 mm, subspherical; pericarp with minute, wart-like papillae (Fig. 23B); seed blackish, slightly keeled; embryo horizontal.

Habitat. Mountain steppes with *Artemisia* sp. div., grasslands, sands, screes or as a weed; 2000–4000 m a.s.l. Common in many parts of Jammu & Kashmir and Himachal Pradesh.

Phenology. Flowering: July-September; fruiting: August-October.

Distribution. See Fig. 24.

General distribution. Temperate Eurasia, North Africa, alien in North America, Australia and New Zealand.

6. *Dysphania geoffreyi* Sukhor, Phytotaxa 203(2): 139 (2015).

Holotype. CHINA, Tibet [Xizang], Lhasa, Daxika, grassy slope, 4150 m a.s.l., herb with green flowers, 5 Sep 1965, *Yong-tian Zhang & Kai-yong Lang* 2663 (PE00510980!). Original text in Chinese.

Description. Annual, 5–50 cm tall, stem erect, often scarcely branched and then only in the upper part, branches directed upwards. Leaves pinnatifid or lobate, rarely toothed, appressed to the stem, up to 2.5 cm long, shortly petiolate (petioles 0.2–1.0 cm); lower leaves caducous at the flowering and fruiting stages. Inflorescence leafy, lateral branches appressed to the stem or obliquely directed, narrowly cylindrical but not spreading, axis covered with short simple hairs up to 0.3 mm long mixed with glandular trichomes. Perianth segments 5, 0.6–0.7 × 0.3–0.4 mm, cristate on dorsal surface (especially on midrib) with numerous large simple stout hairs up to 0.3 mm, the bases of which can sometimes be concrescent, resulting in 2–3-furcate tips, intermixed with yellow sessile glands and scattered glandular hairs (Fig. 23C). Fruit subspherical, 0.5–0.6 mm in diameter; pericarp with tiny volcano-like papillae (Fig. 23D). Seed blackish, keeled, embryo horizontal.

Habitat. Grassy slopes, river banks and sands at 2500–4200(4300–4800) m a.s.l.

Phenology. Flowering: July–September; fruiting: September–October.

Distribution. See Fig. 24.

General distribution. South Tibet, Eastern and Central Himalaya. The species can also be found in India (especially in Arunachal Pradesh) and North Myanmar.

7. *Dysphania tibetica* (A.J.Li) Uotila, Willdenowia 43(1): 67 (2013)

≡*Chenopodium tibeticum* A.J.Li, Fl. Xizang 1: 638 (1983). **Lectotype** (Sukhorukov, designated here): CHINA, Xizang, Gyangze, prope vicum [near a village], 3960 m a.s.l., [5 Sep 1974], Qinghai-Xizang Complex Expedition 74-2077 (PE00024039! isolectotype PE00934045!). In the protologue, Li (in Li and Ma 1983) cited all specimens with the same label as “type” kept at H[erbarium] P[ekinense], now represented by the abbreviation PE. The labels of “holotype” and “isotype” were later assigned by an unknown botanist.

≡*Neobryndium tibeticum* (A.J.Li) M.L.Zhang & G.L.Chu, Pl. Diversity 38(6): 326 (2016).

Description. Annual up to 25 cm, branched from the base with prostrate or ascending stems. Leaves petiolate, up to 4.0 cm, entire to slightly lobate, scarcely pubescent with

Figure 25. SEM micrograph of *Dysphania tibetica* perianth segment, magnification 250 \times .

curved simple hairs. Inflorescence axillary, leafy and short; its branches flattened and slightly winged, usually shortly bifurcate at the top, relatively densely pubescent with semi-appressed or curved simple hairs up to 0.6 mm long, sometimes with scattered glands. Perianth segments 0.7–0.8 × 0.6 mm; their dorsal part with dense indumentum of soft simple hairs (up to 0.3 mm long) and scattered glandular hairs (Fig. 25). Fruits dimorphic: 1.0–1.1 × 0.9 mm, subspherical, pericarp with conical papillae (Fig. 26A, B) and slightly flattened, 0.8–1.0 × 0.7 mm, broadly ovoid, pericarp with crater-like papillae (Fig. 26C, D). Seeds dimorphic: red, slightly keeled, and brownish, not keeled; seed embryo horizontal.

Habitat. Gravelly slopes and ruderal sites at elevations of 3800–5000 m a.s.l. Some specimens from Ladakh contain both *D. tibetica* and *D. himalaica*, and we assume they can often grow together.

Phenology. Flowering: July–September; fruiting: August–October.

Distribution. See Fig. 27.

Specimens examined. CHINA: Xizang: Ngari Prefecture: Gêrzê (Gaize) County, Datan, 4450 m a.s.l., 6 Sep 1974, *Biological Institute Tibet Expedition Team* 4295 (HNWP40801); Gar (Gaer) County, Sogdoi (Suoduo), 4300 m a.s.l., 27 Jul 1976, *Qinghai-Tibet Team* 76-8588 (PE00540036); nr Yanhuqu, 4400 m a.s.l., 24 Aug 1976, *Tibetan Collection Team* 8723 (KUN0265022, PE00540041); Gê'gyai (Geji) County,

General distribution. Himalaya and Tibet.

8. *Dysphania neglecta* Sukhor., Carpologiya Chenopodiaceae: 347 (2014)

Fig. 3

Holotype. NEPAL, Far West Nepal [Midwestern, Karnali Zone], Jumla Prov. [Distr.], Jumla town, 29°16'28"N, 82°11'01"E, weed in the city, 2400 m a.s.l., 23 Sep 2013, A. Sukhorukov 241 (BM000832632! isotype MW0591987!).

Description. Annual up to 100(120) cm tall, green or yellowish-green, very aromatic; stem and leaves densely covered with simple (up to 1.0 mm long) and glandular hairs. Lower leaves long-petiolate, up to 10.0 cm long, pinnatifid, middle and upper leaves shorter, up to 5.0 cm long. Inflorescence up to 45 cm long with villose indumentum consisting of simple (up to 1.0 mm long) hairs partially intermixed with glandular hairs. Perianth segments 5, free, 0.8–1.1 × 0.5 mm long, their dorsal part with glandular hairs (up to 0.125 mm) having scaphoid terminal cell, sometimes also

with scattered simple hairs (Fig. 23E). Fruit 0.7–0.8 mm, subspherical; pericarp with minute wart-like papillae (Fig. 23F). Seed blackish, keeled; embryo horizontal.

Habitat. Limestones, roadsides, along streams at elevations of (1800–1900) 2000–3200 m a.s.l.

Phenology. As in *D. nepalensis* but fruiting 1–2 weeks later, in October (according to the observations in West Nepal).

Distribution. See Fig. 27.

Specimens examined. INDIA: Himachal Pradesh: Simla Distr., Urni-Chim, 9 Jul 1940, M.R. Abbi 2849 (G);

NEPAL: Midwestern: Karnali Zone: [Jumla Distr.] Uthu, E of Jumla, 8000 ft a.s.l., 31 Jul 1952, O. Polunin, W.R. Sykes & L.H.J. Williams 4970 (BM); [Jumla Distr.] 15 km NE from Jumla vill., 1800 m a.s.l., 28 Sep 2010, A. Sukhorukov s.n. (MW); Border of Jumla & Mugu Distr., 1 km from Naurigar vill., 2300 m a.s.l., 26 Sep 2013, A. Sukhorukov s.n. (G); Jumla Distr., Jumla vill., 6 Oct 2014, A. Sukhorukov 585 (BR); Jumla Distr., Sinja, Oct 2014, A. Sukhorukov 57 (M); Mugu Distr., Chauta vill., 2500 m a.s.l., 7 Oct 2014, A. Sukhorukov 599 (MW).

General distribution. West and Central Himalaya (NE India, Nepal). Common in West Nepal.

9. *Dysphania nepalensis* (Colla) Mosyakin & Clements, J. Bot. Res. Inst. Texas 2(1): 428 (2008)

Fig. 3

≡*Chenopodium nepalense* Colla, Herb. Pedem.: 25 (1836). **Holotype:** [NEPAL] ex herb. Birol (TO5972!).

=*Chenopodium multiflorum* Moq. in DC., Prodr. 13(2): 75 (1849). **Lectotype** (designated by Sukhorukov 2012): [INDIA] Ind. Orient. [Uttarakhand], Garhwal, Jun 1845, T.T. Thomson 1324 (K! image available at <http://apps.kew.org/herbcat/getImage.do?imageBarcode=K000898432>; isolectotype BM000629118! image available at <http://www.nhm.ac.uk/emu-classes/class.EMuMedia.php?irn=181039&image=yes&width=705>).

Taxonomic notes. According to the protologue and drawing of the newly described *Neobotrydium ornithopodum* G.L. Chu & M.L. Zhang (Zhang and Zhu 2016), this taxon corresponds to *Dysphania nepalensis* in many details, but we suppose that *D. nepalensis* is not uniform in China. For example, the plants from N, E and NE China as well as those from Mongolia are similar to *D. nepalensis* but have leaves with acute lobes (*D. nepalensis* has obtuse leaf lobes). No other morphological differences between Himalayan/Tibetan and Central Asian populations were found.

Description. Annual up to 50(70) cm, strongly aromatic. Leaves 4.0–10.0 × 2.0–4.0 cm, long-petiolate, pinnatifid or lobate, elliptic-oblong in outline, apex rounded, pubescent mostly abaxially. Inflorescence lax with ± dense indumentum consisting of

simple (up to 1.0 mm long) hairs partially intermixed with glandular hairs. Perianth segments 5, 0.8–1.0 × 0.4–0.5 mm, basally concrescent with stout simple hairs (up to 0.1 mm) forming a keel and yellow subsessile glands (Fig. 23G). Fruit 0.7–0.8 × 0.5 mm, subspherical. Pericarp with minute conical papillae up to 25 µm (Fig. 23H). Seed dark red or almost black, keeled. Embryo horizontal.

Habitat. Grassy hill slopes, disturbed places; 2400–4600 m a.s.l.

Phenology. Flowering: June–September; fruiting: August–November.

Distribution. See Fig. 28.

Specimens examined. BHUTAN: [Thimphu & Paro Districts] Thimphu & Paro rivers, 2400 m a.s.l., 14 Aug 1963, *N.P. Balakrishnan* 1195 (CAL); [Bumthang Distr.] Bumthang, 2600 m a.s.l., 6 Jun 1992, *C. Parker* 7176 (E00051985);

General distribution. Himalaya (southwards to Yunnan), Tibetan Plateau and Pamir Mountains. Widespread in Nepal.

Excluded species

***Dysphania schraderiana* (Schult.) Mosyakin & Clemants, Ukr. Bot. Zhurn. 59(4): 383 (2002)**

≡*Chenopodium schraderianum* Schult. in Roem. & Schult., Syst. Veg., ed. 15(6): 260 (1820).
= *Chenopodium foetidum* Schrad., Mag. Neuest. Entd. Berlin 2: 79 (1808) nom. illegit., non Lam. 1779.

Notes. This species, which is distributed in East Africa and Arabia and found as alien in many (sub)tropical areas of the world, is absent in our area. All records (Zhu et al. 2003) belong to other (native) *Dysphania* species, mostly *D. nepalensis*.

8. *Teloxys* Moq., Ann. Sci. Nat., Bot. sér. 2, 1: 289 (1834)

Teloxys aristata (L.) Moq. (Type).

Description. Annual up to 25 cm forming tumble-weed habit, non-aromatic, highly branched from the base, branches usually terminating with acicular apices, glabrous or with short papillae and white glandular hairs (mostly present in lower stem parts). Leaves up to 6.0 cm long, narrowly oblong or spatulate, sessile or with petiole-like base, entire, often folded on the ventral side. Inflorescences usually terminate with aristae, sometimes (in wet habitats) without acicular apices; flowers solitary in the axils of falsely dichotomous branches. Perianth segments 5, free at base, with slightly keeled midrib, hyaline or pinkish, glabrous. Styles 2(3). Fruit 0.7–0.8 mm, compressedly spherical. Pericarp tightly adjoining the seed coat and separating from it when rubbed, without papillae. Seeds reddish-black, keeled. Embryo horizontal, rarely obliquely or vertically orientated.

One species mostly distributed in Central Asia and alien in many parts of temperate Eurasia and North America.

1. *Teloxys aristata* (L.) Moq., Ann. Sci. Nat. Bot., sér. 2, 1: 289 (1834)

≡*Chenopodium aristatum* L., Sp. Pl.: 221 (1753). **Lectotype** (designated by Iamonico and Jarvis 2012): Herb. Linn. 313.24 (LINN! image available at <http://linnean-online.org/3149/>).

≡*Dysphania aristata* (L.) Mosyakin & Clemants, Ukrainsk. Bot. Zhurn. 59(4): 383 (2002).

=*Chenopodium virginicum* L., Sp. Pl.: 222 (1753). **Lectotype** (designated by Reveal in Jarvis (2007)): Herb. Linn. 313.25 (LINN, image available at <http://linnean-online.org/3150/>).

Taxonomic note. An ecological race of *T. aristata* without aristae mostly occurring in wet habitats.

Description. See the genus description.

Habitat. Gravelly substrates at elevations 3000–4000 m a.s.l. A rare plant in Himalaya.

Phenology. Flowering: July-September; fruiting: August-October.

Distribution. See Fig. 29.

Specimens examined. CHINA: Xizang: Qamdo Prefecture: [Zhag'yab (Chaya) County] Gyitang (Jitang), 3000 m a.s.l., 20 Sep 1976, Wu et al. 6002 (KUN0587074);

NEPAL: Western: Dhaulagiri Zone: Mustang Distr., Khinga, 3100 m a.s.l., 21 Aug 1994, S. Noshiro et al. 9485511 (E00435336); Mustang Distr., Khinga, 24 Sep 1994, Nakarmi 180/1994 (TUCH); Mustang Distr., Lower Chalungpa Khola, 28°54'N, 83°47'E, 3300 m a.s.l., 28 Aug 2001, S. & G. Miehe & Koch 01-087-28 (herb. Miehe); Mustang Distr., Dankardzong, 28°50'N, 83°45'E, 3400 m a.s.l., 10 Sep 2001, S. & G. Miehe & Koch 01-133-05 (herb. Miehe).

Figure 29. Distribution map of *Teloxys aristata* (stars) and *Axyris prostrata* (circles).

General distribution. Central Asia, alien and ephemeral in many temperate regions of Eurasia and North America. In some of the herbaria visited, the specimens from Xizang identified as *Chenopodium aristatum* (\equiv *Teloxys aristata*) indeed belong to *Dysphania* species, although its wider occurrence in this province has been predicted. There are no specimens from India, but the species could be found in some areas (especially in Jammu & Kashmir).

Tribe Axyrideae G. Kadereit & Sukhor., Am. J. Bot. 97(10): 1682 (2010)

9. *Axyris* L., Sp. Pl.: 979 (1753)

Lectotype (designated by Jonsell and Jarvis in Jarvis et al. 1993): *Axyris amaranthoides* L.

Description. Monoecious annuals covered with stellate hairs sometimes intermixed with simple multicellular hairs. Leaves short- or long-petiolate, blade ovate, oblong, spatulate or lanceolate, entire, rarely crisp. Male flowers arranged in terminal spike-like inflorescences up to 8.0 cm long, with minute perianths of 3–5 free hyaline segments and with 2–5 stamens; female flowers located in the bract axils, with five perianth segments. Fruits always dimorphic (heterocarpous); pericarp tightly adjoining the seed coat with small ear-like appendages at the apex of the fruit. Seeds also dimorphic (with thick and thin seed-coat testa). Embryo vertical, horseshoe-shaped or annular; perisperm present.

Six species in Eurasia, predominantly in Central Asia; one (*A. amaranthoides*) is found as an alien plant in many parts of Europe and North America. Fruit morphology and anatomy as well as the peculiarities in plant pubescence are considered the most valuable characters for species delimitation (Sukhorukov 2005, 2011).

Key to the species

- 1 Central ray of stellate hairs on the leaves (especially on petioles), the stem and branches 0.7–2.5(3.0) mm long; black fruits subglobose or spheroidal, brown ones compressed **3. *A. sphaerosperma***
- Central ray of stellate hairs (at least of those on the leaves) much shorter (up to 1.0–1.5 mm long); fruits of both (black and brown) types compressed **2**
- 2 Plant with a prominent main stem; branches ascending; brown (or reddish-brown) fruits (1.6)2.0–2.4 mm long, oblong **2. *A. mira***
- Plant without a pronounced main stem; branches prostrate or ascending; brown fruits 1.3–1.8(2.2) mm long, pear-like **1. *A. prostrata***

1. *Axyris prostrata* L., Sp. Pl.: 980 (1753)

Lectotype (designated by Sukhorukov 2005): Herb. Linn. 1101.6 (LINN! image available at <http://linnean-online.org/10715/>).

The synonyms are listed in Sukhorukov (2005).

Description. Annual with several prostrate stems up to 25 cm long; at high elevations (4000–5000 m), the plant often has a pincushion habit with small branches and short internodes. Leaves long-petiolate, spatulate, up to 3.5 cm, entire, with longer (up to 1.5 mm) stellate hairs near the leaf base, substituted in other parts by short-rayed hairs. Male inflorescence up to 2.0 cm. Perianth of the female flowers with scattered simple hairs. All fruits compressed; black fruits 1.5–2.2 mm long, oblong, with hardly noticeable or indistinct ear-like appendages; brown fruits 1.3–1.8(2.2) mm long, pear-like, with small appendages.

Habitat. Stony places, alpine steppes, often between *Kobresia* cushions, ruderal sites; 2800–5500 m a.s.l.

Phenology. Flowering: August–September; fruiting: September–October.

Distribution. See Fig. 29.

(K); **Western: Dhaulagiri Zone:** Mustang [distr.], 14500 ft a.s.l., 5 Aug 1954, *J. Stainton, W.R. Sykes & L.H.J. Williams* 2194 (BM, E). Two additional records from Upper Mustang are reported by Yonekura (2008) (n.v.).

General distribution. Central Asia, Siberia, Himalaya and Tibet. One of the widespread *Axyris* species. Common in Xizang (China) but rare in Central and Eastern Himalaya.

2. *Axyris mira* Sukhor., Willdenowia 41(1): 76 (2011)

Holotype. [INDIA, Uttarakhand] Kumaon, Milam glacier, 12500 feet a.s.l., 28 Aug 1848, R. Strachey & J.R. Winterbottom 2 (LE! isotypes BM! BR!).

Description. Annual up to 40 cm, main stem erect with ascending branches, green or red, densely covered with short-rayed (up to 1.0 mm) stellate hairs at least in its upper part. Leaves short-petiolate, oblong or ovate, up to 6.0 × 2.0 cm, with short-rayed stellate hairs, dark green. Male inflorescence up to 3.0 cm long. Perianth of the female flowers with dense and large simple hairs. All fruits compressed, oblong; black fruits 1.5–1.8 mm long with very small (up to 0.15 mm) appendices on the pericarp that are indistinct in most cases; brown or reddish-brown fruits (1.6)2.0–2.4 mm long.

Habitat. Grassy (sub)alpine vegetation, *Juniperus* communities, sands, sometimes ruderal sites at elevations of 2600–4500 m a.s.l.

Phenology. Flowering: August–September; fruiting: September–early November.

Distribution. See Fig. 30.

General distribution. Himalaya and Tibet.

3. *Axyris sphaerosperma* Fisch. & C.A.Mey. in Fischer, Meyer & Ave-Lallement, Ind. Sem. Hort. Petrop. 6: 46 (1839)

Lectotype (designated by Sukhorukov 2005): [RUSSIA, Altai] “Lecti in regione orientali fl. altaicae Tschuja” [Chuya river valley in Altai], [year] 1839, [anonym s.n.] (LE!).

Description. Annual up to 40 cm, erect; stem with stellate hairs having a large central ray of 0.7–2.5(3.0) mm long, such hairs especially abundant on stems and leaf petioles. Leaves short-petiolate or subsessile, up to 5 cm, oblong. Male inflorescence up to 2.0 cm long. Perianth of the female flowers with sparse, but large simple hairs. Fruits of two types: subglobose, black, 1.4–1.6 mm with hardly noticeable or indistinct ear-like appendices; the second type ± compressed, ovoid, blackish, 1.6–2.0 mm, also with hardly noticeable or indistinct ear-like appendices.

Habitat. Stony places, alpine vegetation, sometimes ruderal sites at elevations of 3000–4000 m a.s.l.

Phenology. Flowering: July–September; fruiting: September–October.

Distribution. See Fig. 30.

Specimens examined. INDIA: Jammu & Kashmir: [Ladakh] Purig [Kargil], Jul 1933, W Koelz (H1038357). The identification of this specimen comprising only young plants is based on the pubescence details (for more, see Sukhorukov 2011).

General distribution. Central Asia, Siberia and Himalaya. The southernmost border of the range is in N Himalaya.

Species excluded

Axyris amaranthoides L., Sp. Pl.: 979 (1753)

Notes. This species was long considered in broader sense by the authors of Himalayan floras (Hooker 1890, Hemsley 1902, Strachey and Duthie 1906, Bamber 1916) and included *Axyris hybrida* and *A. prostrata*. Subsequently all records were re-identified as *A. mira* or *A. prostrata* (Sukhorukov 2011). The southernmost records of *A. amaranthoides* were discovered outside of our region, e.g. in the provinces of Shaanxi, Gansu, Xinjiang in China (Sukhorukov 2014).

Axyris hybrida L., Sp. Pl.: 980 (1753)

Notes. The records of *A. hybrida* in Xizang and Yunnan (Zhu et al. 2003) belong to *A. mira* (Sukhorukov 2011), and the distribution of the former species lies in the northern part of Central Asia (including Asian Russia, Mongolia, E Kazakhstan, Kyrgyzstan, Tajikistan and N and NE China).

***Axyris villosa* Moq. in DC., Prodr. 13(2): 117 (1949)**

Notes. This name is a synonym of *Bassia lasiantha* Freitag & G.Kadereit (Sukhorukov 2011).

10. *Krascheninnikovia* Gueldenst., Nov. Comm. Acad. Petrop. 16: 551 (1772)

K. ceratoides (L.) Gueldenst (Type).

Description. Subshrubs or shrubs up to 2 m (much smaller at higher altitudes). Stem and leaves covered with stellate hairs often turning fulvous when dry. Leaves alternate, short-petiolate, entire, linear, oblong or ovate, basally cuneate to slightly cordate, green. Flowers unisexual (plants monoecious); male flowers agglomerated in dense spike-like inflorescences that terminate the branches, perianth hyaline with 3–5 almost free segments covered with stellate but easily caducous indumentum, stamens 3–5; female flowers positioned below the male ones, enclosed by a cover consisting of two at least halfway fused accrescent bracts with long simple hairs and much smaller stellate hairs. Styles 2. Fruits with hyaline, very thin pericarp covered with scattered stellate hairs. Seeds ~2.0 mm with thin seed coat, perisperm abundant. Embryo vertical, horseshoe-shaped.

One species in the deserts of Eurasia and North America. According to recent investigations (Heklau and Röser 2008), the genus comprises one species.

1. *Krascheninnikovia ceratoides* (L.) Gueldenst., Nov. Comm. Acad. Petrop. 16: 555 (1772)

≡*Axyris ceratoides* L., Sp. Pl.: 979 (1753). **Lectotype** (designated by Hedge 1997): Herb. Linn. 1101.1 (LINN! image available at <http://linnean-online.org/11529/>). The full synonymy is given by Heklau and Röser (2008).

Taxonomic notes. Morphologically, two forms of *K. ceratoides* can be distinguished based on the shape of the leaf base; some specimens in Himalaya have slightly cordate or truncate leaves while others have cuneate leaves. In Tibet, a form with cuneate leaves is found.

Description. See the genus description.

Habitat. Gravelly hill slopes, steppes and cold deserts at elevations of 2700–5300 m (depending on the region), one of the dominants of cold stony deserts (together with *Juniperus* and *Caragana* spp.).

Phenology. Flowering: July–September; fruiting: September–October.

Distribution. See Fig. 31.

General distribution. Widely distributed in the steppes, deserts and alpine vegetation of Eurasia and North America (in the latter region, *K. ceratoides* is represented by subsp. *lanata*).

Subfam. Betoideae Ulbrich in Engler & Prantl, Nat. Pflanzenfam. ed. 2, 16c: 455 (1934)

11. *Acroglochin* Schrad. in Roem. & Schult., Mant.: 69 (1822)

Acroglochin chenopodioides Schrad. (=*A. persicariooides* (Poir.) Moq.) (**Type**).

Description. Glabrous or scarcely pubescent annual up to 50(70) cm, branches often terminating in acicular apices. Leaves long-petiolate, up to 10.0 cm, broadly ovate or ovoid, dentate or erose, teeth straight or incurved, tip mucronate, blades glabrous or sparsely covered with simple, often curved hairs. Inflorescences in the leaf axils, quite short, falsely dichotomous. Perianth of 5 free segments, keeled along midrib. Stamens 2, anthers small, 0.2–0.3 mm, without appendages. Stylopodia concrecent into column in their lower half. Fruit dehiscent by a lid; pericarp white or greenish with several homocellular layers. Seeds dark-red, depressed-globular, ~1.3 mm in diameter, smooth.

One species in Himalaya and West and Central China.

1. *Acroglochin persicariooides* (Poir.) Moq. in DC., Prodr. 13(2): 254 (1849).

=*Amaranthus persicariooides* Poir. in Lam. & Poir., Encycl.: 311 (1810). **Type:** Nepal/Kashmir (not designated, P?).

=*Acroglochin chenopodioides* Schrad. in Roem. & Schult., Mant.: 227 (1822). **Type:** n.v. (existence not certain).

=*Lecanocarpus nepalensis* Nees in Nees & Sinning, Amoen. Bot. Bonn. 2: tab. 2 (1824).

Type: not found.

=*Boehmeria amaranthus* H.Lév., Repert. Spec. Nov. Regni Veg. 11: 550 (1913). **Holotype:** CHINA, Kouy-Tcheou [Guizhou] Prov., environs de Gan-Pin, 29 Aug 1897, Martin & Bodinier s.n. (E00317870!).

=*Amaranthus diandrus* Spreng., Neue Entdeck. Pflanzenk. 3: 20 (1822) syn. nov. **Lectotype** (Sukhorukov, designated here): NEPAL, Sep 1791, Spreng.[el] (L1677349!).

Note. Although *Amaranthus diandrus* has a very clear diagnosis (Sprengel 1822), it was an unresolved name (Das 2016) and is now added to the synonyms of *Acroglochin persicariooides*.

Description. See the genus description.

Habitat. Hill slopes, disturbed areas at elevations of 1700–3200 m.

Phenology. Flowering: July-September; fruiting: August-October.

Distribution. See Fig. 32.

Specimens examined. BHUTAN: Thimphu Distr., Thimphu, 2300 m a.s.l., 1 Oct 1988, *Wood* 6756 (E00168224);

(BM, E, MW, P).

General distribution. Himalaya and Tibet. Common in Central Himalaya at elevations of 2000–2600 m.

Subfam. Corispermoideae Raf., Fl. Tellur. 3: 45 (1837)

12. *Corispermum* L., Sp. Pl.: 4 (1753)

Lectotype (Hitchcock and Green 1929): *Corispermum hyssopifolium* L.

Description. Annuals, branched from the base, often forming tumble-weed habit, covered with branched hairs, usually glabrescent at the fruiting stage. Leaves

Figure 32. Distribution map of *Acroglochin persicarioides*.

sessile, filiform to ovoid, green or greyish, sometimes red from both sides. Perianth absent or of 1–3 hyaline segments. Stamens 1–3, anthers 0.2–0.3 mm long. Styloidia 2 with persistent lower part. Fruit ovoid or roundish, 1.5–6.5 mm, glabrous or covered with branched (usually caducous) hairs, adaxially plain or slightly concave, abaxially convex; marginal wing membranous, well-developed or tiny. Fruit apex roundish, triangular or emarginate. Pericarp either adherent to the seed coat or its outer layer forms wart-like or (rarely) wavy detachments; groups of dark-brown cells filled with tannins are often present in the outer pericarp layer. Seed coat of two or more thin layers.

Fruit anatomy plays the most important role in the diagnostics of the species groups. The following characters can be noted (Sukhorukov 2007b): (1) thickness of the fruit, (2) thickness of the outer pericarp layer, (3) presence of sclereids in the medial fruit part and their quantity and orientation and (4) outline and size of the fruit wing.

The exact species number is still unknown, but it is estimated at approximately 80 (Sukhorukov 2014).

All species encountered in our area are alpine plants growing at elevations of 2800–5000 m.

Key to the species

- | | | |
|---|--|------------------------|
| 1 | Fruit 4.0–5.5 mm long, emarginate at the top, with marginal wing 0.65–1.40 mm..... | 2 |
| — | Fruit up to 3.5(4.0) mm long, wing up to 0.7 mm | 4 |
| 2 | Fruit covered with stellate hairs, pericarp surface often with groups of dark-brown (tanniniferous) cells..... | <i>C. lepidocarpum</i> |
| — | Fruit glabrous | 3 |

- 3 Plant moderately pubescent; bracts recurved; fruit wing 0.65–0.90 mm **6. *C. lhasaense***
- Plant almost glabrous; bracts not or slightly recurved; fruit wing (0.70)0.90–1.40 mm **5. *C. pseudofalcatum***
- 4(1) Plants dwarfish, up to 6 cm high with single stem or with short lateral branches; leaves linear, up to 1.5(2.0) mm wide **2. *C. nanum***
- Plants usually taller, with well-developed lateral branches; leaves linear to oblong **5**
- 5 Fruit apex clearly emarginate, wing 0.45–0.60 mm; bracts often recurved at fruiting stage **1. *C. falcatum***
- Fruit apex rounded or triangular (but slightly emarginate between the styles) **6**
- 6 Fruit 2.8–4.0 mm, apically strongly triangular; stellate hairs on the fruit present or absent; fruit wing 0.3–0.7 mm **4. *C. dutreuilii***
- Fruit up to 3.2 mm long, apically rounded or indistinctly triangular with wing up to 0.45 mm **7**
- 7 Plants almost glabrous; fruit with stellate hairs and sometimes warts **8. *C. gelidum***
- Plants moderately pubescent; fruit glabrous, usually without warts **8**
- 8 Fruit wing ~0.3 mm **9. *C. tibeticum***
- Fruit wing smaller, 0.15–0.30 mm **3. *C. pamiricum***

1. *Corispermum falcatum* Iljin, Izv. Glavn. Bot. Sada SSSR 28: 644 (1929)

Lectotype (Sukhorukov, designated here): [CHINA] Tibet, Gyantse, Jul-Sep 1904, H.J. Walton s.n. (K000898762! isolectotypes E00317867! P04931276! clastotypes G! LE01013342!).

Note. Iljin (1929) indicates two type specimens (“Kew [K] and Vienna Univ. [WU]”) in the protologue. We did not find the material in WU and thus select a lectotype in herbarium K with additional authentic material in other herbaria.

Description. Annual up to 40 cm, slightly pubescent. Leaves lanceolate, oblanceolate or narrowly oblong, often recurved, up to 3.0 × 0.5 cm. Inflorescence elongated, with many flowers. Bracts usually recurved, sickle-shaped, not completely covering the fruit. Fruits 3.5–4.0 × 3.0 mm, glabrous but sometimes with dark-brown cells and scattered warts (Fig. 33A); fruit margin emarginate at the top. Wing 0.45–0.60 mm, denticulate or crisp, narrowly triangular in cross-section. Sclereids in the medium fruit part consist of 1–2 cell layers orientated parallel to the fruit axis.

Habitat. Scree and sandy riverbeds; 3500–4800 m a.s.l.

Phenology. Flowering: July–September; fruiting: August–October.

Distribution. See Fig. 34.

Specimens examined. CHINA: Xizang: Ngari Prefecture: Gar (Gaer) County, 4250 m a.s.l., 29 Jul 1976, *Qinghai-Tibet Team* 76-8613 (PE00540486); Gar (Gaer) County, nr Shiquanhe river, 4250–4300 m a.s.l., 6 Aug 1976, *Qinghai-Tibet Team Vegetation Group*

13429 (PE00540478); **Xigazê Prefecture:** Gyangtse, 28°96'N, 88°8'E, 12 Jul 1953, *P.C. Isoong* 5692 (PE00540346); Raka Tsangpo valley, 4760 m a.s.l., 29°30'N, 86°17'E, 2 Sep 2003, *G. & S. Miehe* 03-062-10 (E00190600); **Lhasa City:** Namtso lake, 30°52'N, 91°03'E, 4720 m a.s.l., 2 Sep 2005, *Nölling & Hanspach* NX05-194-02 (herb. Miehe);

General distribution. Tibet.

2. *Corispermum nanum* Sukhor. & M.Zhang, Phytotaxa 172(2): 84 (2014)

Holotype. CHINA, Xizang, Saga, Nyalam road, 17 Aug 2011, *Yu, Hou & Zhang* 5607 (PE2264191!).

Description. Dwarfish, densely pubescent annual up to 6 cm with a single stem or with short lateral branches. Leaves linear, up to 1.5(2.0) mm wide. Inflorescence very short, with several flowers. Bracts slightly shorter than fruits (fruit margins visible). Fruit ovoid, 2.5–2.7 × 2.0 mm, glabrous, apex rounded and only slightly emarginated

Figure 34. Distribution map of *Corispermum falcatum* (circles), *C. nanum* (stars), *C. pamiricum* (squares) and *C. dutreuilii* var. *montanum* (triangles).

(Fig. 33B); no visible detachments of the pericarp from the seed coat are present. Wing conspicuous (0.3–0.4 mm), entire, triangular in cross-section. Pericarp in medium fruit part without sclereids or with one layer located parallel to the fruit axis.

Habitat. Sandy places at altitudes of 4000–4700 m a.s.l.

Phenology. Flowering: July-September; fruiting: August-October.

Distribution. See Fig. 34.

Specimens examined. CHINA: Xizang: Nagqu Prefecture: Central Plateau, Nagqu to Siling Co (Lake Siling Tso), 31°28'N, 91°0'E, 4580 m a.s.l., lake terraces, 16 Aug 1993, G. & S. Miehe 9488/03 (MSB147355). The tiny individuals looks similar to the type material, but the fruits are dentate (a typical character for all Tibetan species).

General distribution. Endemic to South Tibet.

3. *Corispermum pamiricum* Iljin, Acta Inst. Bot. Acad. Sc. URSS, ser. 1(3): 165 (1937)

Holotype. [TAJIKISTAN] Buchara prov. [Gorno-Badakhshan Autonomous province], Wachan [Vakhan], in valle fl. Pamir pr. castellum Langar-Gisht, ca. 9500 ft a.s.l., in glareosis riparris [Pamir river valley near Langar-Gisht fortress, 9500 ft a.s.l.], 27 Jul 1901, Th. Alexeenko 3217 (LE! with a topotype no. 3216!).

Description. Annual up to 20 cm, usually pubescent. Leaves linear to narrowly oblong, up to 2.0 × 0.5(0.7) cm, with a mucro at the top. Inflorescence short, its branches with 5–15 flowers. Bracts significantly shorter than leaves, ovoid, (almost) completely covering the fruit, sometimes recurved at the fruiting stage. Fruit 2.2–3.0 × 1.7–2.0 mm, 0.40–0.60 mm thick, with entire margin and indistinctly triangular or roundish apex terminating in slightly emarginate beak (Fig. 33C), glabrous and mostly smooth (without detachments), sometimes with groups of dark-brown tanniniferous cells. Wing small,

0.15–0.30 mm, broadly triangular in cross-section. Pericarp without detachments. Sclereids in the medium fruit part composed of 1–2 layers located parallel to the fruit axis.

Habitat. Sandy places at altitudes of 3400–4000 m a.s.l.

Phenology. Flowering: July–September; fruiting: August–October.

Distribution. See Fig. 34.

Specimens examined. CHINA: Xizang: Xigazê Prefecture: Lhazê (Lazi) County, Kabei vill., 4000 m a.s.l., 27 Aug 1961, Zhang 2727 (PE00540415);

INDIA: Jammu & Kashmir: Ladakh, Indus valley, Sham (W), Basgo to Nye, 3400–3440 m a.s.l., 7 Aug 2006, L. Klimeš 6709 (PRA).

General distribution. Tajikistan (Pamir), N Afghanistan, N India and W China (Xizang).

4. *Corispermum dutreuilii* Iljin, Acta Inst. Bot. Acad. Sc. URSS, ser. 1(3): 162 (1937)

Lectotype (Sukhorukov, designated here): [CHINA, Xinjiang, Kashgar Prefecture] Polour, 2582 m a.s.l., 17 Jul 1892, [J.L.] Dutreuil de Rhins s.n. (LE01013341!).

Note. No herbarium is indicated in the protologue (Iljin 1937). We selected the lectotype using a specimen in LE.

Description. Annual up to 20 cm, glabrescent with ascending branches. Leaves linear to oblong (the lower leaves often spatulate), up to 3.0 × 0.6 cm, often recurved with visible white margins and a mucro at the top. Inflorescence elongated, with many flowers. Bracts leaf-like, lanceolate, significantly exceeding the fruit in length and covering it completely laterally. Fruit 2.8–3.5(4.0) × 2.0–2.5 mm, flat or often folded, acute (triangular) apex with verrucose (warty) surface, without stellate hairs (type variety) or with stellate hairs (var. *montanum*) and clearly visible (0.45–0.70 mm) undulate wing that is narrowly triangular in cross-section. Pericarp detachments up to 100 µm. Sclereids in medium fruit part with 1–2 layers located parallel to the fruit axis, rarely with no sclereids.

Distribution. *Corispermum dutreuilii* seems to be the most common species of the genus in Ladakh and NW Xizang. Both varieties can grow together, e.g. in Ladakh (collection numbers 3465 & 3470 for the type variety and 6265 & 6266 for var. *montanum* (PRA)).

Habitat. Sandy riverbeds, stony deserts; 3500–5000 m a.s.l.

Phenology. Flowering: July–early September; fruiting: August–September.

General distribution. West China (Xizang, Xinjiang, Qinghai), North India, Pakistan, Afghanistan, Tajikistan.

Corispermum dutreuilii var. *montanum* Sukhor., Phytotaxa 172(2): 87 (2014)

Note. Fruit warty and additionally covered with stellate hairs (Fig. 33D); fruit thickness 0.6–0.8 mm.

Holotype. CHINA, Tibet, [Ngari pref.], 32°31'N, 80°04'E, Shiquan [Sênggê] river, alt. 3800 m a.s.l., 3 August 1984, *Zhengxi An 1-10092* (XJA!).

Taxonomic note. This variety is close to *C. gelidum* Iljin with the main difference in the fruit length (compare Sukhorukov 2007a, 2007b, Sukhorukov et al. 2014) and both taxa can grow together (PRA!).

Distribution. See Fig. 34.

Specimens examined. INDIA: Jammu & Kashmir: Ladakh, Rupshu Region, Tso Moriri, Pilung La, 4710–4780 m a.s.l., 20 Aug 1999, *L. Klimeš* 588 (PRA); Ladakh, Indus valley, Stot (E) [Stod River valley], Sumdo Gonma to Kiagar La, 4770 m a.s.l., 7 Sep 2003, *L. Klimeš* 3460 (PRA); Ladakh, Rupshu Region, Samad Rakchan, Thukje Gompa, 4860–5000 m a.s.l., 7 Sep 2005, *L. Klimeš* 6265 & 6266 (PRA); Ladakh, Rupshu Region, Tso Moriri, Lema to Peldo, 4550–4560 m a.s.l., 13 Sep 2005, *L. Klimeš* 6306 (PRA).

Corispermum dutreuilii Iljin var. *dutreuilii*

Note. Fruit warty but without stellate hairs (Fig. 33E), thin (0.25–0.50 mm) in cross-section.

Taxonomic note. The type variety can probably be synonymised with *C. hilariae* (Iljin 1936) due to (i) glabrous stems and the same general habit and (ii) triangular fruit tip and presence of warts in some fruits (variable character). The subulate fruit apex, reported as a peculiar characteristic for *C. dutreuilii*, seems to vary in many specimens. If the merger of both species is to be confirmed, *C. hilariae* is the priority name. Here, we maintain the specific rank of *C. dutreuilii*, dividing it into two varieties (also, see comments on *C. dutreuilii* var. *montanum*).

Distribution. See Fig. 35.

Specimens examined. CHINA: Xizang: Ngari Prefecture: Gérzê (Gaize) County, 4250 m a.s.l., Aug 1972, *Li 072* (PE00540329); Rutog (Ritu) County, Ni Yagezu, 4500 m a.s.l., 5 Sep 1976, *Qinghai-Tibet Team 76-9164* (PE00540476); Rutog (Ritu) County, NW Lake Bangong (Pangong Tso), Ni Yagezu, 4500 m a.s.l., 5 Sep 1976, *Qinghai-Tibet Team Vegetation Group 13559* (PE);

INDIA: Jammu & Kashmir: Ladakh, Shauyk & Rupshu valleys, Oct 1847, *T.T. Thomson* s.n. (K); Ladakh, 6 km W of Pangong Tso [Lake], 4250 m a.s.l., 13 Aug 1997, *H. Hartmann 6083* (MSB137929); Ladakh, Rupshu Region, Tso Moriri, between Korzok & Peldo, 4650 m a.s.l., 11 Aug 2001, *L. Klimeš* 1327 (PRA); Ladakh, Pangong Region, Pangong Lake to Chagar Tso, 4300 m a.s.l., 10 Sep 2002, *L. Klimeš* 3465 & 3470 (PRA); Ladakh, Rupshu Region, Samad Rakchan, Thukje Gompa, 4860–5000 m a.s.l., 7 Sep 2005, *L. Klimeš* 6248 (PRA); Ladakh, Rupshu Region, Samad Rakchan, Thukje vill., 4560 m a.s.l., 9 Sep 2005, *L. Klimeš* 6272 (PRA).

Figure 35. Distribution map of *Corispermum dutreuilii* var. *dutreuilii* (circles), *C. pseudofalcatum* (star) and *C. lhasaense* (triangle).

5. *Corispermum pseudofalcatum* Tsien & C.G.Ma in Kung & al., Acta Phytotax. Sin. 16(1): 119 (1978)

Holotype. CHINA, Xizang, vicinity of Xigazê (Rikaze), farmland edge, 3800 m a.s.l., [without exact date] 1960, *Fu Guo-Xun* 789 (PE00934050!).

Description. Annual to 20 cm, branched at base, (almost) glabrous. Leaves lanceolate, oblanceolate or oblong, 10.0–30.0 × 3.0–5.0 mm, continuously turning into imbricate bracts. Inflorescence elongated. Bracts lanceolate, appressed to the stem or obliquely orientated, not or slightly recurved, completely covering the fruit. Fruit 4.5–5.5 mm long, glabrous but with scattered warts and tanniniferous pigments, apically emarginate (Fig. 33F), thick (0.7–1.0 mm). Wing clearly visible (0.70)0.90–1.40 mm, denticulate, narrowly triangular in cross-section. Pericarp detachments not detected. Sclereids in medium fruit part with 1–2 inner layers (orientated parallel to the fruit axis).

Habitat. Scree and sandy riverbeds; 3000–4200 m a.s.l.

Phenology. Flowering: July–September; fruiting: August–October.

Distribution. This species is known only from the type locality (Fig. 35). Both morphological and carpological characters as well as its record in South Tibet indicate its affinity to *C. lhasaense*.

6. *Corispermum lhasaense* Tsien & C.G.Ma in Kung & al., Acta Phytotax. Sin. 16(1): 119 (1978)

Lectotype (Sukhorukov, designated here): CHINA, Xizang, Lhasa, the Sera Monastery, Liushahe river, in riverway of scree and grits, 3760 m a.s.l., 10 Sep 1960, *Fu Guo-Xun* 658 (PE00024043! isolectotypes LE01013344! PE00540403! PE00540404!).

Figure 36. SEM micrographs of *Corispermum* fruits: **A** *C. lhasaense* **B** *C. lepidocarpum* **C** *C. gelidum* **D** *C. tibeticum*. Magnification: 30 \times .

Description. Annual up to 20 cm, glabrescent. Leaves lanceolate, up to 3.0 \times 0.3 cm long. Inflorescence dense, 3–5 cm long. Inflorescence elongated. Bracts oblong to ovoid, moderately recurved or sometimes appressed to the stem, completely cov-

ering the fruit. Fruit $3.8\text{--}4.7 \times 3.0\text{--}3.5$ mm, glabrous (sometimes with dark-brown tanniniferous cells), thick (0.75–0.85 mm) with well-developed wing 0.65–0.90 mm (especially large near the fruit apex; Fig. 36A). Wing irregularly toothed, emarginate, triangular in cross-section. Pericarp without detachments from the seed coat. Sclereids in the medium fruit part consist of 1–3 cell layers orientated parallel to the fruit axis.

Habitat. Scree and sandy riverbeds, 3000–4000 m a.s.l.

Phenology. Flowering: July–September; fruiting: August–October.

Distribution. See Fig. 35.

Specimens examined. CHINA: Xizang: Xigazê Prefecture: Gyangtse, Jul/Sep 1904, H.J. Walton s.n. (BM).

General distribution. Endemic to South Tibet.

7. *Corispermum lepidocarpum* Grubov, Not. Syst. Herb. Inst. Bot. Ac. Sci. URSS 21: 125 (1961)

Holotype. [CHINA, Xizang] SE Tibet, Temo, Tsangpo valley, 9500 ft a.s.l., 6 Sep 1938, F. Ludlow, G. Sherriff & G. Taylor 6227 (BM000950579! isotype E00317866! clastotypes G! LE!).

Description. Annual up to 20 cm, branched at the base, almost glabrous or glabrescent. Leaves lanceolate or linear, $2.0\text{--}4.0 \times 0.2\text{--}0.4$ cm, transforming into imbricate bracts. Inflorescence usually elongated. Bracts lanceolate or linear, often recurved, not completely covering the fruit laterally. Fruits $4.0\text{--}5.0 \times 3.2\text{--}3.5$ mm with stellate hairs, pericarp surface often with groups of dark-brown (visually almost black) tanniniferous cells; fruit apex deeply emarginate with two lateral crown-like outgrowths (Fig. 36B). Wing clearly visible (0.85–1.10 mm), irregularly toothed, narrowly triangular in cross-section. Pericarp detachments not detected. Sclereids in medium fruit part with 1–2 outer layers located perpendicular to the fruit axis and 1–3 inner layers (orientated parallel to the fruit axis).

Habitat. Scree and sandy riverbeds; 3000–4000 m a.s.l.

Phenology. Flowering: July–September; fruiting: August–October.

Distribution. See Fig. 37.

Specimens examined. CHINA: Xizang: Shannan Prefecture: Gyaca (Jiacha) County, 3200 m a.s.l., 25 Aug 1972, *Tibet Chinese Herbal Medicine Survey Team* 4393 (PE00540398); Gonggar (Gongga) County, Jêdêxoi (Jiedexiu) town, 31 Aug 1975, *anonym* 75-1532 (PE01869900, PE01869902); Way from Gyaca (Jiacha) County to Mainling (Milin) County, 3300 m a.s.l., 18 Sep 1975, *Qinghai-Tibet Team* 7953 (PE00540394); Nyingchi Prefecture: Mainling (Milin) County, nr [Pai Town] Xuega, 3200 m a.s.l., 30 Aug 1960, Xia & Zhu 394 (PE00540399); Nang (Lang) County, 3050 m a.s.l., 17 Aug 1972, *Tibet Chinese Herbal Medicine Survey Team* 4413 (PE00540396); Mainling (Milin) County, nr Jiage, 23 Sep 1974, *Qinghai-Tibet Team Vegetation Group* 3368 (PE00540395); Mainling (Milin) County, Pai distr. (Town), Mt. Doxong (Duoxiong), 2980 m a.s.l., 11 Aug 1975, *Qinghai-Tibet Team Additional Group* 751308 (PE00540400, PE00540401).

General distribution. Endemic to South Tibet.

Figure 37. Distribution map of *Corispermum lepidocarpum* (circles), *C. gelidum* (stars) and *C. tibeticum* (triangles).

8. *Corispermum gelidum* Iljin, Fl. USSR 6: 875 (1936)

Corispermum gelidum Iljin, Fl. USSR 6: 875 (1936). **Holotype:** [TAJIKISTAN] In ditione lacum Rang-kul, prope vallem Zor-Burljuk [nr Rang-kul Lake, Zor-Burlyuk valley], 29 Aug 1935, H. Raikova s.n. (TASH – photo! isotype LE!).

=*C. pamiricum* Iljin var. *pilocarpum* Tsien & C.G.Ma in Kung & al., Acta Phytotax. Sin. 16(1): 118 (1978) syn. nov.

Lectotype (Sukhorukov, designated here): CHINA, Xizang, Rutog (Ritu) County, Rabang (Rebang), in lakeside sands, 4360 m a.s.l., 28 Aug 1976, *Qinghai-Tibet Team Vegetation Group 13656-B* (PE00024045! isolectotype PE00640936!).

Taxonomic notes. *Corispermum gelidum* and *C. pamiricum* var. *pilocarpum* are synonymised here for the first time due to the presence of stellate hairs on the fruit surface. Other anatomical characters of the fruit are similar and overlapping (compare with Sukhorukov 2007b, Sukhorukov et al. 2014). However, the authentic specimens of *C. pamiricum* var. *pilocarpum* possess a small (ca. 0.15 mm) fruit wing, whereas the type specimen of *C. gelidum* has a prominent (0.3–0.4 mm) wing.

Description. Annual up to 20 cm, glabrescent. Leaves linear to narrowly oblong, up to 3.0 × 0.5(0.7) cm. Inflorescence short. Bracts shorter than leaves, lanceolate, (almost) completely covering the fruit, appressed to the stem. Fruit 2.6–3.5 × 1.7–2.0 mm, 0.40–0.60 mm thick, flat or folded adaxially, with triangular apex terminating in slightly emarginate beak, with stellate hairs and mostly warty (Fig. 36C), sometimes with groups of dark-brown tanniniferous cells. Wing 0.15–0.45 mm, entire to dentate, broadly triangular in cross-section. Sclereids in the medium fruit part composed of 1–2 layers located parallel to the fruit axis.

Habitat. Sandy places at altitudes of 3500–4800 m.

Phenology. Flowering: July–September; fruiting: August–October.

Distribution. See Fig. 37.

Specimens examined. CHINA: Xizang: Ngari Prefecture: Rutog (Ritu) County, Rabang (Rebang) Distr., 4300 m a.s.l., 28 Aug 1976, *Qinghai-Tibet Team* 76-9128 (PE00540421); Rutog (Ritu) County, Rabang (Rebang) Distr., 4500 m a.s.l., 28 Aug 1976, *Qinghai-Tibet Team Meadow Group* 76-12970 (PE00541028); both specimens were labelled as *Corispermum pamiricum* var. *pilocarpum*;

INDIA: Jammu & Kashmir: Ladakh, Shyok (E), Pangong Lake to Chagar Tso, 4320 m a.s.l., 10 Sep 2002, *L. Klimeš* 2712 (PRA); Ladakh, Shyok (E), Takthak, 4100–4110 m a.s.l., 11 Sep 2002, *L. Klimeš* 2730 (PRA); Ladakh, Rupshu Region, Tso Moriri, 4550–4560 m a.s.l., Lema to Peldo, 13 Sep 2005, *L. Klimeš* 6307 (PRA).

General distribution. Tajikistan (Pamir) and adjacent parts of China, India and Pakistan.

9. *Corispermum tibeticum* Iljin, Izv. Glavn. Bot. Sada SSSR 28: 644 (1929)

Corispermum tibeticum Iljin, Izv. Glavn. Bot. Sada SSSR 28: 644 (1929). **Lectotype** (Sukhorukov, designated here): [probably INDIA, Jammu & Kashmir] Hab. Tibet Occ., alt. 10000–15000 ft a.s.l., [J.D.] Hooker f. & T.T. Thomson s.n. (K! lower right plant). **Note.** The Falconer specimens cited in the protologue as the type material of *C. tibeticum* were labelled by Iljin in 1929 as “an *Corispermum orientale?*” [“whether *C. orientale?*”]. In the protologue (Iljin 1929), the specimens were cited as a type material of *C. tibeticum*, but the Falconer syntype kept at K is not informative and rather deviates from the typical *C. tibeticum* by its almost wingless fruits. We propose to select a lectotype from other specimens (syntypes) cited by Iljin in the protologue. The lectotype designated here shows the pubescent plant with lanceolate or narrowly oblong leaves, fruits with a blackish body and a small wing. Some other collections cited in the protologue (Shayuk Valley, 3 Oct 1847, T.T. Thomson, K; Indus valley, 1 Oct 1847, Hooker & T.T. Thomson, K) and mounted as one specimen are *C. dutreuilii*.

=*C. ladakhianum* Grey-Wilson & Wadhwa, Kew Bull. 42(2): 471 (1987), syn. nov.

Holotype. [INDIA] Jammu & Kashmir, Ladakh, Khardung, 3900 m a.s.l., Aug 1976, *Wadhwa* 59931 (K! isotype BSD000000038!). **Note.** Grey-Wilson and Wadhwa (1987) compared *Corispermum ladakhianum* with *C. lehmannianum*; the latter species grows in the plains of West-Central Asia (most common in Kazakhstan, Uzbekistan and Turkmenistan) and Iran. Other taxa were not mentioned in the discussion. *Corispermum ladakhianum* matches *C. tibeticum* in all characters.

Taxonomic notes. Although *C. tibeticum* looks very similar to *C. hyssopifolium* (and many old specimens were previously identified as such), the fruit anatomy does not

confirm the close affinity of both species. As stated earlier, the fruits of *C. hyssopifolium* always have several sclereid layers in different locations (Sukhorukov 2007b, 2014) and the distribution patterns of *C. tibeticum* and *C. hyssopifolium* are very distant (North Himalaya and Eastern Europe, respectively). Some specimens from Ladakh, that were examined, possess elongated fruits appearing similar to those of the *C. declinatum* group. However, the fruit anatomy of *C. tibeticum* drastically differs from that of *C. declinatum* Stephan ex Iljin or *C. tylotocarpum* Hance (for more, see Sukhorukov 2007a, 2007b) and it is typical of *C. tibeticum* and relatives (*C. dutreuilii* Iljin, *C. hilariæ* Iljin and *C. pamiricum* Iljin). Some forms of *C. tibeticum* with the triangular fruit beak appear similar to *C. dutreuilii*.

The presence of *C. declinatum* and *C. tylotocarpum* (syn.: *C. gmelinii* Bunge) in Tibet and North Himalaya (L. Klimeš, in herb.) is not confirmed.

Description. Annual up to 30 cm, moderately pubescent, looking greyish even at maturity and the fruiting stage. Leaves lanceolate, spatulate or narrowly oblong, up to $4.0 \times 0.5(0.7)$ cm with a mucro at the top. Inflorescence elongated, its branches with many (up to 30) flowers. Bracts significantly shorter than leaves, ovoid, (almost) completely covering the fruit. Fruit $2.8\text{--}3.2 \times 2.5$ mm, 0.50–0.65 mm thick, body sometimes blackish with entire margin and broadly triangular apex terminating in slightly emarginate beak, glabrous and mostly smooth (without detachments), sometimes with small warts (Fig. 36D). Marginal wing clearly expressed, ~0.30 mm, triangular in cross-section. Sclereids in the medium fruit part in one layer located parallel to the fruit axis or rarely absent.

Habitat. Sandy riverbeds and stony deserts; 3000–4800 m a.s.l.

Phenology. Flowering: July–September; fruiting: August–early October.

Distribution. See Fig. 37.

Specimens examined. CHINA: Xizang: Ngari Prefecture: [Gar County] Pangong Lake, 4430 m a.s.l., 24 Jul 1892, Pekcz s.n. (LE); [Burang County] Manasarovar Lake (Mapam Yumtso), south shore of Langa Tso (Lake), $30^{\circ}30'N$, $81^{\circ}17'E$, 4680 m a.s.l., 29 Aug 1993, G. & S. Miehe 9598/03 (MSB147354);

INDIA: Jammu & Kashmir: Ladakh, nr Leh, Sep 1848, 10000–15000 ft a.s.l., T.T. Thomson s.n. (K); Nubra [valley], Sep 1848, 10000–15000 ft a.s.l., T.T. Thomson s.n. (K); [Leh distr.] Nurla, 10000–11000 ft a.s.l., Jul 1905, A. Meebold 3957 (G); Ladakh, Saspol, 3320 m a.s.l., 8 Sep 1989, L. Klimeš & Sintek s.n. (MSB137930); Ladakh, Rupshu Region, Tso Moriri, 4650 m a.s.l., 11 Aug 2001, L. Klimeš 1328 (PRA); Ladakh, Pangong Region, Spangmik to Pangong Lake, 4300 m a.s.l., 10 Sep 2002, L. Klimeš 10 & 13 (PRA); Ladakh, Indus valley, Sham (W), Mebtah, 3700–3750 m a.s.l., 22 Sep 2005, L. Klimeš 6494 (PRA); Ladakh, Indus valley, Sham (W), Sumdo to Phobe La, 3420–3500 m a.s.l., 24 Sep 2005, L. Klimeš 6519 (PRA); Ladakh, Indus valley, Sham (W), Nimu, 3180 m a.s.l., 24 Sep 2006, L. Klimeš 7377 (PRA).

General distribution. N Himalaya, NW Tibet, Karakoram and Pamir.

Species excluded

Corispermum korovinii Iljin, Izv. Glavn. Bot. Sada SSSR 28: 641 (1929)

Note. The species is reported in Klimeš and Dickoré (2005) from Ladakh, India. All examined specimens (PRA) belong to other *Corispermum* species and the distribution area of *C. korovinii* covers the plains of Eastern Kazakhstan and West China (Xinjiang).

13. *Agriophyllum* M.Bieb. ex C.A.Mey., Verz. Pfl. Cauc. Casp. Meer: 163 (1831)

Agriophyllum arenarium M.Bieb. (=*Agriophyllum pungens* (Vahl) Link ex A.Dietr.) (Type).

Description. Annuals, usually with tumble-weed habit, covered with dendroid hairs (Fig. 38) and sometimes with simple hairs. Leaves sessile or petiolate with linear to orbicular blades, acuminate, soft at earlier stages then usually turning hard and stout, persistent. Inflorescences short, capituliform; each flower with a stout bract, ebracteolate, mostly bisexual. Perianth of 1–5 free hyaline segments. Stamens 1–5. Fruits glabrous or pubescent with easily caducous dendroid hairs. Pericarp leathery, thin and ruptured in the medium fruit portion. The lower part of stylodia persistent and hardened, often with lateral horn-like outgrowths. Seeds ovoid, lenticular, yellow or brownish, sometimes with dark tanniniferous spots. Embryo vertical, horseshoe-shaped; perisperm copious.

Eight species (including a new species described below) distributed in Irano-Turanian region (7 spp.) and Tibet (1 sp.).

1. *Agriophyllum tibeticum* Sukhor. sp. nov.

urn:lsid:ipni.org:names:77194255-1

Agriophyllum tibeticum Sukhor. sp. nov. **Holotype:** [CHINA, Xizang, Nyingchi Prefecture] SE Tibet, Kongbo [Gongpo'gyamda] County, Lilung-Gacha, 29°07'N, 93°41'E, 9800 ft a.s.l., on sand dunes, 5 Oct 1938, F. Ludlow, G. Sherriff & G. Taylor 7180 (BM001209885! isotypes – E! G!). Fig. 38.

=*Agriophyllum squarrosum* auct. non (L.) Moq.

Taxonomic notes. The specimens of *A. tibeticum* were identified as *A. arenarium* or *A. squarrosum* (both names refer to *A. pungens*) because of their similar habit and oblong leaves. However, the stems of *A. tibeticum* are much shorter and their upper parts are covered with long (up to 2.5 mm), persistent dendroid hairs (or at least not easily caducous) at the fruiting stage. The hairs of *A. pungens* and *A. gobicum* are up to 0.8–1.0 mm long and easily caducous at the fruiting stage. Additionally, these two species are distributed in the plains of Central Asia: *A. pungens* is widely distributed in the Irano-Turanian Region and *A. gobicum* is localised in Mongolia and North China. Thus,

Figure 38. Holotype of *Agriophyllum tibeticum* Sukhor. sp. nov. (BM001209885).

Figure 39. SEM micrographs: **A** *Agriophyllum tibeticum*, hairs from the stem **B** *A. tibeticum*, concave side of the seed **C** *A. tibeticum*, convex side of the seed **D** *Suaeda olufsenii*, fruit enclosed in the perianth; **E, F** *S. olufsenii*, red seed. Magnification: 50× (**A, B**), 75× (**C, D**), 100× (**E**), 500× (**F**).

there is a significant gap between the distribution of typically alpine *A. tibeticum* and all other species of the genus.

Description. Annual up to 20(30) cm with tumble-weed habit; stem very densely pubescent with dendroid hairs (up to 2.5 mm in length, Fig. 39A) and often whitish when young with partially persistent hairs in the fruiting stage. Lower leaves oblong or oblong-lanceolate, continuously decreasing in size and shape in the inflorescence, 2.0–8.0 × 0.5–1.5 cm, tapered in petiole, with (5)6–10 prominent nerves, densely pubescent when young. Inflorescence leafy; flower clusters remote in the lower part of the inflorescence and densely arranged in the upper part. Anthers ~0.3 mm. Pericarp covered with dendroid hairs, glabrescent at fruiting. Seed lens-shaped (Fig. 39B, C), 1.9–2.1 mm × 1.3–1.4 mm, yellow with brownish tanniniferous spots.

Differs from the two related species, *A. pungens* (Vahl) Link ex A.Dietr. and *A. gobicum* Bunge (if the latter is accepted at the specific rank), by persistent dendroid pubescence (with longer hairs) in the inflorescence at the fruiting stage as well as by its disjunct distribution in South Tibet.

Habitat. Sand dunes and stony riverbeds; 2800–3700 m a.s.l.

Phenology. Flowering: August–September; fruiting: September–early October.

Distribution. See Fig. 40.

Specimens examined. CHINA: Xizang: Lhasa City: Vicinity of Lhasa, Sep 1939, Richardson 360 (BM); Lhasa, 5 Sep 1943, F. Ludlow & G. Sherriff 9921 (BM, E, LE); Shannan Prefecture: Gonggar (Gongga) County, river bank of the Yarlung Zangbo (River), 3600 m a.s.l., 23 Sep 1975, Qinghai-Tibet Team 7659 (KUN0586383); [Nê-dong (Naidong) County] Zêtang (Zedang), 3500 m a.s.l., 10 Aug 1977, B.Z. Description. Annuals, subshrubs or shrubs, glabrous or slightly pubescent with curved or short straight hairs. Stems green or red. Leaves terete or semi-terete, rarely flattened, obtuse or mucronate, with diverse anatomy and photosynthetic pathways. Inflorescences branched, flowers in clusters subtended by a leaf-bract and tiny hyaline bracteoles. Perianth of 5 segments or lobes, sometimes fused almost to the top, free or adhering to the fruit. Fruit glabrous, without papillae. Seeds monomorphic or (in annual species) dimorphic (structural heterosperry). Embryo horizontal or vertical, sometimes both types are present on the same individual (spatial heterosperry).

More than 100 species distributed in all continents.

1. *Suaeda olufsenii* Paulsen, Vidensk. Meddel. Naturhist. Foren. Kjøbenhavn [s.n.]: 194 (1903)

Fig. 41

Suaeda olufsenii Paulsen, Vidensk. Meddel. Naturhist. Foren. Kjøbenhavn [s.n.]: 194 (1903). **Holotype**. [TAJIKISTAN, Badakhshan] Pamir, in angustiis Chargush [Khargush], in litore salso lacus [on the saline shore of a little lake], 4200 m a.s.l., 2 Sep 1898, O. Paulsen 1230 (C10009368, image seen! isotype LE n.v.).
 ≡*S. corniculata* (C.A.Mey.) Bunge var. *olufsenii* (Paulsen) G.L.Chu in Kung & Tsien, Fl. Reipubl. Pop. Sin. 25(2): 128 (1979).

Taxonomic notes. The examined specimens have perianth with unequal projections at the fruiting stage that is consistent with the species description by Paulsen (1903). However, Lomonosova and Freitag (2008) indicated equal projections of the perianth segments based on the specimens collected in the Altai Mountains. We assume that plants from Altai are different from the populations growing in Pamir, Tibet and North Himalaya.

Description. Annual up to 25 cm, glabrous or young parts are slightly pubescent with curved hairs, branched from the base with prostrate stems. Leaves up to 15.0

× 2.0–4.0 mm, semi-terete without or with an inconspicuous mucro. Inflorescence bracteous. Bracts rather flat, ovoid or elliptical. Flowers 3–12 in clusters. Perianth at fruiting stage with unequal horizontal wing-like projections (Fig. 39D). Stigmas 2. Seeds dimorphic: dark-red seeds 0.9–1.0 mm in diameter, marginally acutish, surface with remarkable polygonal sculpture (Fig. 39E, F), brown seeds 1.1–1.5 mm, with rugose surface.

Habitat. Scree, sands and disturbed places; 3400–5300 m a.s.l.

Phenology. Flowering: July–September; fruiting: September–October.

Distribution. See Fig. 40.

General distribution. W China, N India, N Pakistan and Tajikistan; also reported from E Kazakhstan, Kyrgyzstan, Mongolia and Russia (Altai).

Species excluded

Suaeda microsperma Fenzl in Lebed., Fl. Ross. 3(2): 785 (1851)

Note. Cited in Dhar and Kachroo (1983), Chowdhery (1984) and Paul (2012) for Indian Himalaya.

The data on the presence of this species in India is erroneous since it is distributed in the plains of Central Asia (Kazakhstan and Uzbekistan to the foothills of Tajikistan in the south). All *Suaeda* specimens from North India belong to *S. olufsenii*.

Subfam. Camphorosmoideae A.J.Scott, Fedd. Repert. 89(2–3): 102 (1978)

15. *Bassia* All., Mélanges Philos. Math. Soc. Roy. Turin 3: 177 (1766)

Bassia aegyptiaca All. (=*B. muricata* (L.) Asch.) (**Type**).

Description. Annuals or subshrubs with simple, alternate, entire, flattened or terete leaves with diverse types of Kranz anatomy. Inflorescence spiciform, leafy, formed of few-flowered axillary clusters. Flowers solitary or in clusters of 2–5, hermaphrodite or unisexual (mostly female) with 5 perianth segments that are free or half-way connate and which develop wing-like, spiny or tuberculate outgrowths at the fruiting stage or rarely lack outgrowths. Style very short with 2–3 filiform stigmas. Fruit round or ovoid, compressed with smooth pericarp ± tightly adjoining the seed coat; seeds with horizontal horseshoe-shaped embryo; perisperm abundant.

Note. The genera that are now included in *Bassia* are cited in Kadereit and Freitag (2011).

~20 species in Eurasia and North Africa.

Key to the species

- 1 Plants subshrubs or sub-shrublets; leaves semi-terete; bracts equal to or slightly larger than flower clusters..... **3. *B. prostrata***
- Plants annuals; leaves flattened; bracts clearly longer than the flower clusters..... **2**
- 2 Plants whitish or grey due to dense pubescence on stem, leaves and perianth ...
..... **2. *B. odontoptera***
- Plants green or reddish-green, pubescent or almost glabrous; perianth glabrous or ciliate **1. *B. scoparia***

1. *Bassia scoparia* (L.) A.J.Scott, Fedd. Report. 89(2–3): 108 (1978)

≡*Chenopodium scoparium* L., Sp. Pl.: 221 (1753). **Lectotype** (designated by Jafri and Rateeb 1978); Herb. Linn. 313.20 (LINN! image available at <http://linnean-online.org/3145/>).

≡*Kochia scoparia* (L.) Schrad., Neues J. Bot. 3(3–4): 85 (1809). Comprehensive list of synonymous names of *B. scoparia* is presented in Sukhorukov (2014). Here we add an additional synonym.

=*Bassia fiedleri* Aellen in Hegi, Ill. Fl. Mitt.-Eur., ed. 2, 3(2): 713 (1961) syn. nov. Aellen (in Hegi 1961) stated a new name instead of *Bassia divaricata* (Kar. & Kir.) Kuntze (1891) [now *Grubovia dasypylla* (Fisch. & C.A.Mey.) Freitag & Kadereit], non *Bassia divaricata* F. Muell. (1882). The name *Bassia fiedleri* was accepted as a synonym of *Grubovia dasypylla* (Kadereit and Freitag 2011). However, the analysis of the material in G collected by O. Fiedler in Germany (as an alien plant) and treated by P. Aellen clearly shows that *Bassia fiedleri* is conspecific with *Bassia scoparia*.

Description. Erect annual up to 150(200) cm; stem and branches green or sometimes reddish, moderately to densely covered by long, soft, simple multicellular hairs. Leaves flat, 20.0–50.0(80.0) × 1.5–7.0(10.0) mm, subpetiolate at base, narrowly oblong to lanceolate or linear, three-nerved, densely pilose. Bracts longer than flower clusters. Inflorescences spiciform, foliose, axes with fine spreading hairs. Flowers mostly in clusters of 2–5, unisexual or hermaphrodite, surrounded by basal tufts of hairs or not. Perianth fused halfway, ciliate or glabrous, with small horizontal wings or tubercles at the fruiting stage, sometimes without any projections. Fruit compressedly ovoid, ~2.0 mm long, dark brown. Seeds with horizontal embryo.

Habitat. Disturbed areas at elevations of 2500–3500 m, stony slopes or sands; rare.

Phenology. Flowering: July–September; fruiting: August–October.

Distribution. See Fig. 42.

Specimens examined. CHINA: Xizang: Nyingchi Prefecture: Nang (Lang) County, Zhongda, 3150 m a.s.l., cultivated, 3 Sep 1972, *Tibet Chinese Herbal Medicine Survey Team* 4520 (PE00526535);

General distribution. Most likely, originated in Central Asia (Kazakhstan to West China and Mongolia), alien elsewhere in the temperate parts of Eurasia, Australia and Americas.

2. *Bassia odontoptera* (Schrenk) Freitag & G.Kadereit, Taxon 60(1): 73 (2011)

≡*Kochia odontoptera* Schrenk, Bull. Acad. Petersb. 1: 361 (1843). **Lectotype** (Sukhorukov, designated here): [probably East KAZAKHSTAN] “desert. Songor.” [Songorian desert] leg. Schrenk s.n. (P04994622!).

=*Kochia iranica* Bornm., Bull. Herb. Boissier, ser. 2, 8: 546 (1908). **Syntypes:** Persia [IRAN], prov. Kerman, Kerman, in cultis, 1900 m a.s.l., 20 Aug 1892, *J. Bornmüller* 5074 (P032634! LE! MW!) as *Salsola iranica*.

≡*Bassia iranica* (Bornm.) Fedde. Repert. 17: 276 (1921).

Description. Annual up to 25 cm with often reddish stems covered with spreading hairs. Leaves up to 1.0 cm, oblong to ovate, densely covered with (semi)appressed hairs (both

stem and leaves are partially glabrescent at fruiting). Inflorescences bracteose with bracts slightly longer than the flower clusters. Flowers (2–5) in clusters. Perianth fused up to the half, densely pubescent with wing-like projections at fruiting, 3.0–5.0 mm across (with wings). Wings white or reddish, entire to erose-dentate or lobate (but not pinnatisect). Fruit compressedly ovoid, 0.7–0.8 mm long. Seeds with horizontal embryo.

Habitat. Sands and stony plateaux at elevations of 2700–4700 m; common in many places of Jammu and Kashmir as indicated by the collectors.

Phenology. Flowering: July–September; fruiting: August–early October.

Distribution. See Fig. 42.

General distribution. Iran, Afghanistan, North Pakistan and Central Asia (Turkmenistan and Tajikistan).

3. *Bassia prostrata* (L.) A.J.Scott, Fedd. Report. 89(2–3): 108 (1978)

≡*Salsola prostrata* L., Sp. Pl.: 222 (1753). **Lectotype** (Tan 1997): Herb. Linn. No. 315.15 (LINN).

≡*Kochia prostrata* (L.) Schrad., Neues J. Bot. 3(3–4): 85 (1809). Other synonyms are listed in Sukhorukov (2014).

Description. Subshrub or sub-shrublet up to 100 cm (much smaller in mountainous areas) with basally branched caudex. Leaves up to 25 mm long, linear or lanceolate, densely pubescent. Bracts reduced, mostly up to 5 mm long, equal to or slightly longer than flower clusters. Perianth densely pubescent, fused up to the half, with wing-like projections of white or reddish colour at fruiting stage turning brown before dissemination, 3.5–6.0 mm across (including wings). Seeds with horizontal embryo.

Habitat. Subalpine vegetation (often in *Artemisia* steppes) and scree at altitudes of 3000–4500 m a.s.l.; locally common.

Figure 43. Distribution map of *Bassia prostrata* (stars) and *Grubovia dasypylla* (circles).

Phenology. Flowering: July–September; fruiting: August–October.

Distribution. See Fig. 43.

General distribution. Temperate Eurasia.

Excluded species

Bassia indica (Wight) A.J.Scott, Fedd. Report. 89(2–3): 89 (1978)

≡*Kochia indica* Wight, Icon. PL. Ind. Orient. 5: tab. 1791 (1852). **Lectotype** (Sukhorukov, designated here): [INDIA, Tamil Nadu state] Coimbatore, Oct 1847, herb. Wight 2479 (K000400258!).

Notes. This species was reported for Jammu & Kashmir and Himachal Pradesh, India (Dhar and Kachroo 1983, Chowdhery 1984), but all examined specimens belong to

Bassia scoparia and other Chenopodiaceae. However, the presence of *B. indica* is possible in the foothills of North Himalaya (0–1500 m a.s.l.), as it is known from neighbouring areas, e.g. state of Haryana, India (BSD! LE!) and Punjab Province, Pakistan (K!).

16. *Grubovia* Freitag & G. Kadereit, Taxon 60(1): 72 (2011)

Grubovia dasypylla (Fisch. & C.A.Mey.) Freitag & G.Kadereit (**Type**).

Description. Annuals, usually with tumble-weed habit. Stems and leaves with white, simple multicellular hairs that are appressed and obliquely orientated and with scattered yellow short hairs mostly located in the leaf axils. Leaves terete, green, obtuse, with water-storage tissue and C₃-type anatomy. Flowers in leaf axils, solitary or in pairs. Perianth of 5 at least half-way concrescent segments, usually pilose; all or three of five segments develop wing-like or spiny projections. Stamens 5, with small anthers. Fruit with hyaline pericarp adherent to the seed coat. Seed embryo horizontal. Perisperm abundant.

Here, we indicate for the first time that the presence of short yellow hairs is the remarkable morphological characteristic of *Grubovia* that is important for the delimitation of this genus. *Grubovia* comprises three species mostly distributed in Central Asia. *Grubovia dasypylla* has the largest distribution that also includes Tibet and North Himalaya.

1. *Grubovia dasypylla* (Fisch. & C.A.Mey.) Freitag & G.Kadereit, Taxon 60(1): 72 (2011)

≡*Bassia divaricata* (Kar. & Kir.) Kuntze, Revis. Gen. Pl. 2: 546 (1891) nom. illegit., non F.Muell. 1882.

Taxonomic note. Both *Kochia dasypylla* and *Echinopsilon divaricatus* were described in the same year (1841). The priority of the name *Kochia dasypylla* (now *Grubovia dasypylla*)

Figure 44. *Grubovia dasypylla*: **A** general view of the plant at blooming stage **B** close-up of the flowers. Photographs by Prashant Awale (near Khalsar village, Nubra valley, Jammu & Kashmir, India, September 2011).

is based on the publication date of the book by Fischer and Meyer (22 July 1841) against the name *Echinopsilon divaricatum* published by Karelin and Kirilloff in the *Bulletin de la Société Imperiale des Naturalistes de Moscou*, vol. 4 (8 September 1841).

Description. Annuals up to 30 cm with tumble-weed habit. Stems red or green, pilose at younger stage and moderately glabrescent at fruiting (white or greyish hairs often turning fulvous after drying). Leaves 1.0–4.0 × 0.1–0.3 cm, with appressed or spreading white hairs up to 6–7 mm long. Perianth segments 5, pilose (Fig. 44B), sometimes glabrescent at fruiting stage with spiny (subulate or acicular), star-like projections up to 3.0 mm long that can be glabrous or with simple white hairs. Stamens 5. Fruit ovoid.

Habitat. Rocky or sandy areas at elevations of 3000–4600 m. A rare plant in North India (Hartmann 1983, sub *Bassia fiedleri*).

Phenology. Flowering: July–September; fruiting: August–October.

Distribution. See Fig. 43.

General distribution. N Himalaya, Tibet and Central Asia.

Subfam. Salsoloideae Raf., Fl. Tellur. 3: 45 (1837)

The subfamily (excluding Camphorosmoideae) contains at least 400 species divided into ~30 genera.

Tribe Salsoleae

17. *Salsola* L., Sp. Pl.: 222 (1753)

S. kali L. (**Type**).

=*Kali* Miller, Gard. Dict. Abr., ed. 4: [715] (1754). **Type:** *K. turgidum* (Dumort.) Gutermann, Phyton (Horn) 51(1): 98 (2011).

Taxonomic notes. The taxa related to *Salsola kali* were considered within the reinstated genus *Kali* (Akhani et al. 2007), which was accepted in subsequent taxonomic treatments (Gutermann 2011, Sukhorukov et al. 2011, Sukhorukov 2014, Brullo et al. 2015, Sukhorukov et al. 2016b). However, Mosyakin et al. (2014, 2017) presented some arguments in favour of a recent nomenclatural proposal to conserve the generic name *Salsola* with *S. kali* (=*Kali turgidum*) as a conserved type. The Nomenclature Committee for Vascular Plants did not reach a consensus regarding the recommenda-

tion or rejection of this proposal (Applequist 2016), but the accepted type of the genus *Salsola* is *S. kali* under the new Art. 10.5–10.7 of the ICN (Turland et al. 2018).

Description. Annuals or subshrubs, glabrous or papillate, with tufts of simple curved hairs in the leaf axils. Leaves mostly alternate or lower leaves opposite, semi-terete or terete, sometimes flattened, usually less than 5 mm in width, stiff or fleshy, with a persistent yellowish mucro up to 3.5–4.0 mm long. Bracts longer than bracteoles or equal in size. Flowers of two types: some located below the main inflorescence and arranged in clusters mostly consisting of two female flowers supported by concrescent and basally hardened bracts and bracteoles, rarely clusters one-flowered (these fall off with bracts and bracteoles), perianth r-shaped, usually with small wings, tubercles or without any projections in the flexure; flowers of the second type grouped in the main inflorescence, hermaphrodite, each flower supported by a free bract and two bracteoles (rarely concrescent), r-shaped or tubuliform at fruiting (in the latter case, the segments in their upper part are convergent, forming a stout or hyaline conus that covers the fruit from above). Perianth of (4)5 segments, with well-developed, equal or unequal wings or tubercles at the fruiting stage. Stamens (in the hermaphrodite flowers) 5, divided in the lower half, without prominent appendages at the tip of the anthers. Stigmas 2, usually equal to style (or a style is very short). Fruits dry or somewhat fleshy in the upper part. Seeds with horizontal or obliquely orientated embryo (sometimes seems to be vertical due to anacrostylly). Perisperm absent.

Approximately 22 species in the steppes, seashores and deserts of Eurasia, North America, Africa and Australia.

Key to the species

- 1 Bracts appressed to the stem; perianth (of the flowers located in the main inflorescence) at fruiting with tubercles; alternatively, two (out of five) perianth segments bear short wings up to 1.5 mm long **2. *S. collina***
- Bracts (often horizontally) spreading, rarely appressed (some specimens of *S. monoptera*); at least 1 of 5 segments with well-developed wing(s) **2**
- 2 Perianth segment closest to the bract with conspicuous wing, the others with tubercles; all outgrowths orientated vertically **6. *S. monoptera***
- All 5 or at least 2 or 3 segments with horizontally reflexed or obliquely orientated outgrowths **3**
- 3 Leaves linear to lanceolate, (1.0)2.0–4.0(5.0) mm in width; perianth conus slightly hardened **5. *S. austrotibetica***
- Leaves filiform to linear, not exceeding 1.5(2) mm in width (except the broad leaf base); perianth conus not expressed or hyaline **4**
- 4 Bract and bracteoles basally gibbous; winged perianth 2.0–3.0 mm across; only 2 or 3 (of 5) perianth segments with well-developed wings (other segments with tubercles only); anthers 0.3–0.5 mm long **1. *S. bartmannii***
- Bract and bracteoles usually not gibbous; winged perianth 3.5–10.0 mm across; all perianth segments form equal or slightly unequal wings; anthers 0.5–0.8 mm long **5**

- 5 Plant usually densely papillate; perianth with wings 3.5–6.0 mm across.
Plants of Central Himalaya and Tibet **3. *S. jacquemontii***
- Plant glabrous or papillate; perianth with wings (6.0)7.0–10.0 mm across.
Plants of North Himalaya **4. *S. tragus***

1. *Salsola hartmannii* Sukhor., sp. nov.

urn:lsid:ipni.org:names:77194256-1

Fig. 45

Holotype. [INDIA, Jammu & Kashmir] E-Ladakh, Alpine Steppe mit *Artemisia minor*, ca. 1 km W oberhalb Kiagar Tso [alpine steppe with *Artemisia minor*, ca. 1 km W above Kiagar Tso], 4720 m a.s.l., 27 Aug 1997, H. Hartmann 6080 (G00410003! isotype – MSB160560!).

Taxonomic notes. The new species was formerly identified as *S. jacquemontii* or *S. collina*. In many characters (e.g. tiny anthers, small outgrowths of the perianth segments), *Salsola hartmannii* resembles *S. monoptera*, but the latter species has only one well-expressed, wing-like projection on a segment closest to the bract, whereas projections on other segments are much smaller (in the form of tubercles). Additionally, the gibbous bracts and bracteoles are exceptionally rare in *S. monoptera*. In contrast, *S. hartmannii* possesses gibbous bracts and bracteoles and two or three perianth segments develop tiny, but clearly visible wings. The new species is also similar to *S. jacquemontii* but has smaller anthers and a smaller diameter of the entire diaspore (winged perianth enclosing the fruit), which is hidden within the subtending bract and bracteoles.

The gibbous bract and bracteoles cannot be considered as strong characteristic features of *S. hartmannii*; some specimens of *S. jacquemontii* may possess such a shape of the bracts and bracteoles. All three species, *S. monoptera*, *S. hartmannii* and *S. jacquemontii*, are morphologically related. *Salsola collina* is morphologically distant from these species, having appressed bracts without clearly expressed wings on the perianth at fruiting. The distribution patterns are also different: *S. monoptera* is widespread in Central Asia and Tibet, *S. hartmannii* seems to be localised in North Himalaya and Karakoram and *S. jacquemontii* is found in Central Himalaya and Tibet. The presence of *S. jacquemontii* and *S. collina* in North Himalaya (Rilke 1999) is not confirmed.

Description. Annual with prostrate or ascending stems up to 15 cm long, glabrous or scarcely papillate. Leaves terete, 10–20 × 1.0–1.5 mm. Flowers in axillary clusters and arranged in the main inflorescence. Flower clusters (located below the main inflorescence) abundant and consist of two flowers covered with bracts and bracteoles that are connate almost to the top and basally gibbous; perianth segments membranous, fimbriate, r-shaped, their tips more or less appressed to each other, not hardened and not forming a tight conus, with white, small tubercles 0.3–0.5 mm long in the flexure; styles with stigmas ca. 0.5 mm; fruits 1.2–1.6 mm, depressed roundish. Flowers in the main inflorescence with (almost) free, basally gibbous bract and bracteoles, hermaphrodite; perianth segments 5, membranous, fimbriate, r-shaped at the fruiting stage, < 2.5 mm long, above the flexure soft, hyaline, horizontally ori-

Figure 45. Holotype of *Salsola hartmannii* Sukhor. sp. nov. (G).

Figure 46. Distribution map of *Salsola hartmannii* (circles), *S. collina* (stars) and *S. jacquemontii* (triangles).

entated and not forming a distinct conus; 2 or 3 (of 5) segments develop wing-like appendages (up to 1.5 mm long) that are located almost horizontally or obliquely, two other segments develop tubercles only; the whole diaspore with the perianth wings is 2.0–3.0 mm across and is hidden within the bract and bracteoles; anthers 0.3–0.5 mm long; styles with stigmas ca. 1 mm; fruits lenticular, 1.1–1.5 mm. Seeds with horizontal or obliquely orientated embryo.

Habitat. Gravelly or sandy substrates at altitudes of 3500–5200 m. The species seems to be common in Ladakh and Spiti Valley.

Phenology. Flowering: August–September; fruiting: September–October.

Etymology: The specific epithet is after Hans Hartmann, a Swiss geobotanist who provided significant contributions to the flora and vegetation of North India.

Distribution. See Fig. 46.

2. *Salsola collina* Pall., Ill. Pl.: 34 (1803)

Salsola collina Pall., Ill. Pl.: 34 (1803). **Lectotype** (Rilke 1999): Habitat in Siberia, *Pallas* s.n. (LIV, isotype BM!).

≡*Salsola kali* L. subsp. *collina* (Pall.) O.Bolós & Vigo, Butl. Inst. Catalana Hist. Nat., Secc. Bot. 38(1): 89 (1974).

≡*Kali collinum* (Pall.) Akhani & Roalson, Int. J. Pl. Sci. 168(6): 946 (2007). The full list of the synonyms is presented in Rilke (1999).

Description. Erect or prostrate (in mountainous areas) annual up to 70 cm, stems reddish, glabrous or scarcely papillate. Lower leaves up to $80.0 \times 0.5\text{--}1.0$ mm, much shorter in the middle and upper stem parts, linear or filiform, with a mucro 0.6–2.0 mm long. Flowers in axillary clusters and arranged in the main inflorescence. Flower clusters (located below the main inflorescence) abundant, consisting of two flowers surrounded by bracts and bracteoles that are connate almost to the top and not gibbous basally; perianth segments of each flower membranous, glabrous, r-shaped, their tips appressed to each other, hardened and not forming a tight conus, with white, small tubercles 0.3–0.5 mm long or without any projections in the flexure; styles with stigmas ca. 1.0 mm; fruits 1.0–1.3 mm, depressed roundish. Flowers in the main inflorescence with (almost) free, basally not gibbous bract and bracteoles (that are appressed to the stem), hermaphrodite; perianth segments membranous, glabrous, r-shaped at fruiting stage, (1.5)2.0–2.5 mm long, membranous above the flexure and not forming a distinct conus; two abaxial segments usually have short erose wings (up to 1.0(1.5) × 1.5 mm), their tips (above outgrowths) hyaline and not stout; anthers 0.6–0.9 mm long; styles with stigmas ca. 1.0 mm; fruits lenticular, 1.1–1.5 mm. Seed seems to be vertical (due to anacrostly) but is indeed horizontal.

Habitat. Cold stony deserts at elevations of 2800–4400 m.

Phenology. Flowering: July–September; fruiting: September–October.

Distribution. See Fig. 46.

Specimens examined. CHINA: Xizang: Xigazê Prefecture: Lhazê (Lazi) County, Kabei vill., 4000 m a.s.l., 27 Aug 1961, *Zhang* 2726 (PE02048027); Gyangzê (Jiangzi) County, 3960 m a.s.l., 7 Sep 1974, *Qinghai-Tibet Team* 74-2107 (PE00166821); Lhasa City: Lhasa, Aug 1939, *Richardson* 338 (BM); W of Lhasa, 3700 m a.s.l., 3 Sep 1960, *Xia* 815 (PE00166830); Lhasa, 3800 m a.s.l., 16 Aug 1965, *Zhang* & *Lang* 1533 (PE00166814); N of Lhasa, 3700–3800 m a.s.l., 23 Aug 1984, *R.F.Huang* CG-552 (HNWP109096); Nyingchi Prefecture: [Zayü (Chayu) County] Cawarong (Chawalong), 3000 m a.s.l., Aug 1935, *C.W. Wang* 65180

(PE00166833); [Gongbo'gyamda (Gongbujiangda) County] Songduo to Apei, 3800 m a.s.l., 16 Sep 1965, *Zhang & Lang* 2747 (PE00166817); Mainling (Milin) County, Jiage, 3200 m a.s.l., 11 Jul 1972, *Tibet Chinese Herbal Medicine Survey Team* 3686 (PE00166824); Zayü (Chayu) County, Zha'na [close to Cawarong], 2000 m a.s.l., 3 Oct 1982, *Qinghai-Tibet Team* 10919 (PE01063467); **Qamdo Prefecture:** [Baxoi (Basu) County] Bamda (Bangda) to Zogang (Zuogong), 3700 m a.s.l., 29 Aug 1976, *anonym* 76-574 (PE00513543).

The specimens from India reported by Dhar and Kachroo (1983) and Klimeš and Dickoré (2005) were not examined by us. All investigated specimens belong to *Salsola hartmannii* and *S. tragus*. However, *S. collina* is present in North Pakistan and its occurrence in Jammu and Kashmir is predictable.

General distribution. Temperate Eurasia and East Europe; alien in West/Central Europe, Scandinavia and North America.

3. *Salsola jacquemontii* Moq. in DC., Prodr. 13(2): 188 (1849)

Fig. 47

Taxonomic notes. The morphological differences between *S. tragus* and *S. jacquemontii* are vague (also, see the diagnostic key in Rilke 1999). The latter species, however, is encountered in the Central Himalaya and South Tibet, where *S. tragus* is absent. Generally, *S. jacquemontii* has smaller anthers, perianth and wings at the fruiting stage than those of *S. tragus*. Additionally, the stem is usually straight in *S. tragus* and prostrate in *S. jacquemontii*, although some forms with a straight stem were also observed by AS at lower altitudes (2600–3000 m) in Central Nepal.

Description. Annual up to 50 cm, prostrate or rarely with prominent upright main stem. Stem and branches green or reddish, densely covered with papillae. Lower leaves up to 35 × 2 mm (upper leaves much shorter, up to 15.0 mm long), with a mucro (1.5)2.0–3.0 mm long. Flowers in axillary clusters and arranged in the main

Figure 47. *Salsola jacquemontii* plant at fruiting stage. Photograph by A. Sukhorukov (near Kagbeni vill., Dhaulagiri zone, Nepal, September 2009).

inflorescence. Clusters (located below the main inflorescence) consist of two female flowers supported by a bract and two bracteoles that are connate almost to the top and usually not gibbous at the base; perianth segments membranous, fimbriate, r-shaped with their tips appressed to each other, not hardened and not forming a tight conus, with small, reddish or white tubercles up to 0.6 mm long in the flexure; styles with stigmas ca. 1.0 mm long; fruits 1.3–1.6 mm in diameter. Flowers in the main inflorescence with (almost) free, usually not gibbous, bract and bracteoles, hermaphrodite; perianth segments membranous, fimbriate, r-shaped at fruiting stage, < 2.5 mm long, soft above the flexure, hyaline, 0.6–0.8 mm long, horizontally appressed and not forming a distinct conus; three segments with horizontally orientated wing-like appendages (< 3.0 mm long), two other segments with tubercles only (the entire diaspore with the perianth wings is 3.5–6.0 mm across); anthers 0.5–0.7 mm long; styles with stigmas ca. 1.0–1.5 mm long; fruits lenticular, 1.1–1.5 mm in diameter. Seeds with horizontal or obliquely orientated embryo.

Habitat. Gravelly substrates, limestone at elevations of 2600–4200 m.

Phenology. Flowering: July–September; fruiting: August–October.

Distribution. See Fig. 46.

General distribution. Central Himalaya and Tibet.

4. *Salsola tragus* L., Cent. Pl. 2: 13 (1756)

Salsola tragus L., Cent. Pl. 2: 13 (1756). **Lectotype** (designated by Degen 1937): Herb. Linn. 315.3 (LINN). The list of the synonyms is extremely large for this species (Rilke 1999), but some varieties and species described from Europe or Central Asia require additional study.

Description. Annual up to 70 cm high. Stem branched from the base, finely papillate or glabrous as well as the leaves. Leaves 20.0–80.0 × 1.0–2.0 mm, linear, with a mucro (1.5)2.0–3.5 mm long. Flowers in axillary clusters and arranged in the main inflorescence. Clusters (usually located below the main inflorescence) consist of two often unequal female flowers, each flower supported by a bract and two bracteoles and additional bracts are sometimes present in the clusters; bracts and bracteoles fused in their basal part; perianth segments free, membranous, r-shaped, their tips appressed to each other, not hardened, not forming a conus, with small or hardly noticeable, red to pinkish wings in the flexure; styles with stigmas ca. 1.5 mm long; fruits 1.0–1.6 mm, depressed roundish to ovoid. Flowers in the main inflorescence with a free bract and two bracteoles (shorter than bract or equal in length), hermaphrodite; perianth segments membranous, tubuliform (not r-shaped), 3.0–4.0 mm long at fruiting stage, their lower part marginally glabrous or minutely fimbriate; segment tips hyaline, forming a convergent, glabrous conus 1.0–1.5 mm long with well-developed, horizontally located or slightly recurved, entire to crisp wings in the flexure; three outer segments develop roundish wings and two inner segments have narrower, lanceolate outgrowths (the whole diaspore with the perianth wings is (6.0)7.0–10.0 mm across); anthers 0.6–0.8 mm long (on specimens from our region); styles with stigmas 1.0–1.5 mm; fruits 1.5–1.8 mm, roundish. Seeds with horizontal embryo.

Habitat. Rocky or sandy places at altitudes of 2700–4200 m.

Phenology. Flowering: July–September; fruiting: August–October.

Distribution. See Fig. 48.

Specimens examined. CHINA: Xizang: Ngari Prefecture: Zanda (Zhada) County, Diyag (Diya), Gulang, 2900 m a.s.l., 2 Jul 1976, *Qinghai-Tibet Team 76-8156* (PE00528531);

INDIA: Jammu & Kashmir: Shayuk [Shyok] valley, 30 Oct 1847, *T.T. Thomson* s.n. (K); Nubra valley toward Leh, 15 Sep 1848, *T.T. Thomson* s.n. (K); Srinagar, [without date] *Benham* s.n. (BM000016607); Ladakh, Leh to Kaltse, Jul 1856, *Schlagintweit 1034 & 1507* (BM000016644, P05007283); Ladakh, Nubra valley, Diskit, 3200 m a.s.l., 16 Aug 1998, *G.S. Goraya* et al. 1091 (BSD); Ladakh, Tirit vill., 3200 m a.s.l., 18 Aug 1976, *B.M. Wadhwa* 59979 (BSD); Leh, 3620 m a.s.l., 13 Jul 1992, *H. Hartmann 4018* (G); Ladakh, Indus valley, Leh, 3650 m a.s.l., 13 Aug 1999, *L. Klimeš* 463 (PRA); Ladakh, Shyok (W & C), Agham, 3320 m a.s.l., 16 Sep 2001, *L. Klimeš* 1877 (PRA); Ladakh, Suru Region, Kargil, 2720–2860 m a.s.l., 18 Sep 2004, *L. Klimeš* 4977 (PRA).

General distribution. Temperate Eurasia, North Africa, alien in the Americas and Australia.

Figure 48. Distribution map of *Salsola tragus* (circles), *S. austrotibetica* (stars) and *S. monoptera* (triangles).

5. *Salsola austrotibetica* Sukhor., sp. nov.

urn:lsid:ipni.org:names:77194257-1

=*Salsola ikonnikovii* sensu Rilke (1999) non Iljin; *Salsola tragus* sensu Zhu et al.

(2003) non L. Holotype: [CHINA, Xizang, Nyingchi Prefecture, Gongbo'gyamda County] Kongbo Province [Kongpo Region], Sang, Tsangpo valley, 29°29'N, 94°14'E, 9500 ft a.s.l., 25 Jun 1938, F. Ludlow, G. Sherriff & G. Taylor 4983 (BM000016629). Fig. 49.

Taxonomic notes. The hardness of the conus (perianth part above the wings or tubercles at the fruiting stage) is a very important trait for identifying the representatives of the *Salsola* type section (ex-*Kali*), which is widely used in taxonomic treatments (e.g. Iljin 1936, Tzvelev 1996, Rilke 1999). The length of the conus seems to be another important characteristic for the taxonomy of this group. All specimens of *S. austrotibetica* were formerly identified as *Salsola ikonnikovii* or rarely *S. tragus* (incl. *S. pestifer*). The identification of the Tibetan specimens as *S. ikonnikovii* (Rilke 1999) was mostly based on the similar broader and stiff leaves. *Salsola ikonnikovii* was formerly considered more broadly with a vast distribution covering Central Asia and Tibet (Rilke 1999). Although some other Central Asiatic species were included in *S. ikonnikovii* (*S. beticolor* Iljin, *S. centralasiatica* Iljin, *S. microkali* Popov, *S. potaninii* Iljin and *S. chinghaiensis* A.J.Li), the specific status of these taxa must be re-evaluated following extensive molecular and morphological investigations. All southernmost records of *Salsola ikonnikovii* cited by Rilke (1999) from Tibet [Xizang] are here considered *Salsola austrotibetica*.

Salsola ikonnikovii s. str. is characterised by a large (10–20 cm) main inflorescence with very densely arranged flowers, winged perianth 5.0–8.0 mm in diameter and peri-

anth segments forming a narrowly triangular and stiff conus of (2)2.5–3.5 mm long. In contrast, the new species has a much smaller (up to 12 cm) inflorescence, perianth with wings 4.0–5.0 mm across and triangular and slightly hardened perianth conus 1.5–2.0 mm long. All plants in the PE herbarium were identified as *Salsola ruthenica* [\equiv *S. tragus*], another similar-looking species. However, linear or filiform leaves and a completely hyaline perianth conus distinguish *S. tragus* from both *S. ikonnikovii* and *S. austrotibetica*.

The distribution area of *Salsola austrotibetica* is restricted to South Tibet (Fig. 48) and that of *S. ikonnikovii* covers Mongolia and the northernmost provinces of China (Nei Mongol, Ningxia and Gansu).

Description. Annual up to 40 cm high. Stem straight, branched from the base with ascending lateral shoots; stem and leaves finely papillate. Leaves on the main stem remote (with internodes 20–40 mm long), 20–50 mm long, 1.0–4.0(5.0) mm wide above the broad base, slightly flattened, lanceolate to linear, thick, with a mucro (1.0)1.5–2.5 mm long. Flowers in axillary clusters and arranged in the main inflorescence. Flower clusters (usually located below the main inflorescence) consist of two often unequal female flowers, each flower supported by a bract and two bracteoles, sometimes additional bracts are present in the clusters; bracts and bracteoles fused in their basal part; perianth segments of each flower membranous, r-shaped, their tips appressed to each other, not hardened, not forming a conus, with red to pinkish, small or hardly noticeable wing-like tubercles in the flexure; styles with stigmas ca. 1.5 mm long; fruits 1.0 to 1.6 mm, depressed roundish to ovoid. Flowers in the main inflorescence lax, hermaphrodite, with two bracteoles (slightly shorter than bract) and a free bract having a broad (up to 1.0 mm) white margin; perianth segments membranous, tubuliform (not r-shaped), 1.7–2.2 mm at flowering stage and elongated to 4.0–5.0 mm at fruiting, their lower part marginally glabrous or finely fimbriate; segment tips slightly hardened but not hyaline, forming a convergent, glabrous conus 1.5–2.0 mm long, with well-developed, obliquely orientated, unequal, erose to lobate wings in the flexure; the whole diaspore with the perianth wings is 4.0–5.0 mm across; anthers 0.7–0.8 mm; styles with stigmas 1.3–1.7 mm; fruit ~1.5 mm, depressed roundish. Seeds with horizontal embryo.

Habitat. Sand dunes, gravelly substrates, and sometimes in dump areas at altitudes of 2700–4200 m.

Phenology. Flowering: July-August; fruiting: August-September.

Distribution. See Fig. 48.

Specimens examined. CHINA: Xizang: Xigazê Prefecture: Gyantse, 1904, H.J. Walton s.n. (BM); Lhasa City: Reting, 60 miles N of Lhasa, 13000 ft a.s.l., 31 Jul 1942, F. Ludlow & G. Sherriff 8986 (BM, LE); Lhasa, nr the 49th Hospital, 3700 m a.s.l., 7 Sep 1960, Xia & Zhu 816 (PE00528532, PE00528533); Shannan Prefecture: Gonggar (Gongga) County, Jêdêxoi (Jiedexiu) town, 3600 m a.s.l., 31 Aug 1975, *anon-*ym 75-1536 (PE00541011, PE00541012, PE00541013).

General distribution. Endemic to South Tibet.

Figure 49. Holotype of *Salsola austrotibetica* Sukhor. sp. nov. (BM0000016629).

6. *Salsola monoptera* Bunge, Bull. Acad. Imp. Sci. Saint-Pétersbourg 25: 364 (1879)

Salsola monoptera Bunge, Bull. Acad. Imp. Sci. Saint-Pétersbourg 25: 364 (1879). **Lectotype** (Sukhorukov, designated here): Mongolia chinensis in itineris ad Chinam, [year] 1840 [*Tatarinow s.n.*] (LE!). **Note.** Bunge (1879) did not state a herbarium for the type specimen. Rilke (1999) and Grubov (2000) indicated that the holotype is in LE, but the Bunge herbarium is also deposited in some other herbaria, especially in G and P. Choosing a lectotype, we follow the suggestion of McNeill (2014) since no collection number and herbarium are indicated in the protologue.
 ≡*Kali monoptera* (Bunge) Lomon., Konsp. Fl. Aziatsk. Rossii: 101 (2012).

Description. Annuals, very branched from the base. Stems prostrate or ascending, green, often with reddish stripes, papillate or almost glabrous. Leaves very densely arranged, linear, 10.0–25.0 × 0.4–1.0 mm, leaf mucro ~1.0 mm long. Flowers in axillary clusters and arranged in the main inflorescence. Flower clusters (located below the main inflorescence) consist of one flower supported by a bract and two bracteoles, sometimes additional bracts are present in the clusters; bracts and bracteoles half fused or less; perianth segments membranous, r-shaped with their tips appressed to each other, not hardened, not forming a conus, with pinkish or white, small or hardly noticeable wing-like tubercles in the flexure, one segment (closest to the bract) with small tuberculate (up to 1.0 mm) projection; styles with stigmas ca. 1.0 mm long; fruits 1.0–1.2 mm, depressed roundish to ovoid. Flowers in the main inflorescence with a free bract and two bracteoles (slightly shorter than bract), hermaphrodite; perianth segments free, membranous, r-shaped, horizontally appressed and not forming a conus above the flexure; wing-like appendages vertically located and clearly unequal (the most prominent, entire to lobate < 1.5 mm long, wing develops on the segment closest to the bract (rarely in other positions), other segments have smaller entire tubercles up to 1 mm or no projections at all); the whole diaspore with the perianth wings 1.5–2.3 mm across; anthers 0.3–0.4 mm long; styles with stigmas ~1.0 mm; fruit 1.1–1.4 mm, lenticular. Seeds with horizontally or obliquely orientated embryo.

Habitat. Rocky places and sands at an altitude of 3500–4800 m.

Phenology. Flowering: July–September; fruiting: August–October.

Distribution. See Fig. 48.

Specimens examined. CHINA: Xizang: Ngari Prefecture: Rutog County, 4300 m a.s.l., 3 Sep 1990, Y. Fei et al. 702 (KUN0275168); Manasarovar Lake (Mapam Yumtso), Langa Tso (Lake), 30°30'N, 81°17'E, 4680 m a.s.l., 29 Aug 1993, G. & S. Miehe 9598/11 (herb. Miehe); Nagqu Prefecture: Shuanghu County, 4800 m a.s.l., 26 Aug 1976, Qinghai-Tibet Team Vegetation Group 12348 (PE00515977); Upper Salween basin, Nagqu–Damxung, 21 km S of Nagqu, 31°22'N, 91°56'E, 4570 m a.s.l., 4 Sep 1989, B. Dickoré 4681 (MSB157875, MSB161896); Central Plateau, Siling Tso (Lake), Nagqu, 31°24'N, 90°1'E, 4700 m a.s.l., 13 Aug 1993, G. & S. Miehe 9474/07 (MSB147391); S of Xiketang Lake, 31°57'N, 90°46'E, 4680 m a.s.l., 18 Aug 2005, Nölling & Hanspach NX05-123-04 (herb. Miehe); Xigazê Prefecture: [Yadong County] nr Phari, 14500 ft a.s.l., Sep 1938, B.J. Gould 1625 (K);

INDIA (new record for the country): Ladakh, Whisky Nallah, 30 Aug 1970, U.C. Bhattacharyya 40939 (BSD).

General distribution. Central Asia and South Siberia. The species was probably first collected in Xizang in the 1980s–1990s (Rilke 1999), but it is not mentioned in Zhu et al. (2003). The records cited below expand the distribution of *S. monoptera* to the south (compare to Rilke 1999).

18. *Halogeton* C.A.Mey. in Ledeb., Icon. Pl. 1: 10 (1829)

H. glomeratus (M.Bieb.) C.A.Mey. (**Type**).

Description. Annual up to 30 cm with a tumble-weed habit at the fruiting stage; young plants often woolly due to abundant curved simple hairs in the leaf axils. Stem and leaves glabrous or shortly papillate. Leaves terete, up to 15 mm long, with a yellowish, easily caducous mucro up to 5.0 mm. Flowers covered with a bract and two bracteoles with two types of perianth (most of the flowers with five hyaline perianth segments (up to 3.0 mm long) with an orbicular white or pink wing (2.0–3.0 mm, sometimes 0.7–1.5 mm in diameter) near their tips; a small part of the flowers with 5 perianth segments hardened almost to the top without any projections or tuberculate). Stamens 2–3. Anthers 0.5–0.6 mm long. Fruit 1.0–1.2 mm. Seeds with vertical embryo, with the radicula pointing upwards. Perisperm absent.

One species widely distributed in Central Asia, South Siberia, Tibet and North Himalaya.

1. *Halogeton glomeratus* (M.Bieb.) C.A.Mey. in Ledeb., Fl. Altaic. 1: 378 (1829) Fig. 50

≡*Anabasis glomerata* M.Bieb., Mém. Soc. Nat. Mosc. 1: 110 (1808). **Lectotype** (designated here by Sukhorukov): Ex Sibiria [From Siberia], Salesow [Zalesov] (LE!).

=*H. tibeticus* Bunge, Anabas. Rev.: 94 (1862). **Lectotype** (Sukhorukov, designated here): [probably N INDIA or NW Xizang] In regione temperata regni Tibetan occidentalis, alt. 12[000]–14000' [ft a.s.l.], T.T. Thomson s.n. (K! isolectotypes G00177348! G00177349!).

=*H. kashmirianus* Grey-Wilson & Wadhwa, Kew Bull. 42(2): 473 (1987). **Holotype**: INDIA, Jammu & Kashmir, Leh, towards Indus river, 3505 m a.s.l., Aug 1976, Wadhwa 59345 (K, not found; isotype – BSD000000040!).

Taxonomic notes. The differences between *H. glomeratus*, *H. tibeticus* and *H. kashmirianus* are not clearly expressed. The plants growing in the mountainous areas of Pamir northwards through Karakoram to Ladakh are finely papillate-pubescent (*H. tibeticus* s. str.) compared with the populations from the Central Asian plains. A dis-

tinct trait indicated in the protologue of *H. tibeticus* (Bunge 1862), the arachoidous stems in young plants, is characteristic for *H. glomeratus* and the stems are glabrescent at maturity. The triangular, erose-dentate perianth wings of *H. tibeticus* compared with *H. glomeratus* (Iljin 1936) rather refer to the wing variability of *H. glomeratus* (as in many *Salsola* s. str.) and such a wing shape is indeed rare in the examined specimens. The same characters are reported as differences between *H. kashmirianus* and *H. glomeratus*, but the name and characters of *H. tibeticus* are not mentioned and discussed in the description of *H. kashmirianus* (Grey-Wilson and Wadhwa 1987). Interestingly, the specimens kept at Kew, especially those collected at different stages and mounted on to one herbarium sheet, were identified differently. The younger, pubescent plants were identified by Grey-Wilson and Wadhwa as *H. kashmirianus*, but the glabrescent plants collected at the fruiting stage are labelled as *H. glomeratus*. The isotype of *H. kashmirianus* (BSD!) represents a part of the plant without papillae on the stem and both the papillate and non-papillate plants are present in Himalaya and Tibet. Due to the absence of the clear characters that allow *H. glomeratus*, *H. kashmirianus* and *H. tibeticus* to be separated, we prefer to treat *H. glomeratus* in a broader sense.

The specimens of *H. glomeratus* from the deserts of adjacent Xinjiang (China) are not morphologically uniform and have much smaller perianth segments and wings (0.7–1.5 mm in diameter [*H. kunlunense* Sukhor. (nomen)]) than those (1.3–1.6 mm long) of *H. glomeratus*.

Description. See genus description.

Habitat. Rocky or sandy, often disturbed places at altitudes of 3200–4500 m. Common in Ladakh.

Phenology. Flowering: July-September; fruiting: August-October.

Distribution. See Fig. 51.

Specimens examined. CHINA: Xizang: Ngari Prefecture: Rutog (Ritu) County, Lake Bangong (Pangong Tso), 4250 m a.s.l., 3 Sep 1976, *Qinghai-Tibet Team 76-9140, 76-8741 & 76-9142* (PE00540886, PE00540889, PE00540893, KUN0587507, KUN0587509, KUN0587511); Zanda (Zhada) County, Zanda valley, 3600 m a.s.l., 31°29'58"N, 79°45'56"E, 6 Sep 2012, *FLPH Tibet Expedition 12-0260* (PE01967943), 12-0262 (PE01967946), 12-0263 (PE01967925);

Klimeš 2699 (PRA); Ladakh, Indus valley, Sham, 3420–3500 m a.s.l., 24 Sep 2005, L. Klimeš 6518 (PRA).

General distribution. Central Asia, Siberia, North Himalaya and Tibet; as alien in North America.

19. *Haloxylon* Bunge, Rel. Lehm. (Mém. Sav. Etrang. Petersb.) 7: 468 (1851)

Haloxylon Bunge, Rel. Lehm. (Mém. Sav. Etrang. Petersb.) 7: 468 (1851). **Lectotype** (Pfeiffer 1874): *H. ammodendron* (C.A.Mey.) Bunge.

Description. Sub-shrubs, shrubs or trees; branches cylindrical, jointed. Leaves opposite, minute or rudimentary, connate. Flowers small, hermaphrodite, axillary and usually solitary, two-bracteolate. Perianth segments 5, free or connate in the lower part with spreading, scarious wings near the tip. Stamens usually 5. Anthers muticous. Staminodes 5, membranous, thin and glabrous, united with the bases of filaments into a lobed, cup-like disc. Ovary with short style and 2–3(5) stigmas. Fruit included in open perianth, globular-depressed, slightly fleshy in the upper part. Seeds horizontal with spirally coiled embryo. Perisperm absent.

Five to seven species mostly distributed in the Irano-Turanian region. The position of *Haloxylon thomsonii* within this genus is still pending due to its unusual life history (sub-shrublet) and one-layered stem epidermis (all other species possess two-layered epidermis).

Figure 52. Reproductive shoot of *Haloxylon thomsonii* at fruiting stage, with prominent perianth wings. Photograph by H. Hartmann (Jammu & Kashmir, India, 1995).

1. *Haloxylon thomsonii* Bunge in Boiss., Flora Orient. 4(2): 950 (1879)

Fig. 52

Haloxylon thomsonii Bunge in Boiss., Flora Orient. 4(2): 950 (1879). **Type:** n.v.

≡*Arthrophytum thomsonii* (Bunge) Ulbr. in Engler & Harms, Nat. Pflanzenfam., ed. 2, 16c: 570 (1934).

≡*Hammada thomsonii* (Bunge) Iljin, Bot. Zhurn. 33: 583 (1948). *Hammada cashemiriana* Iljin in herb. LE (nomen).

Description. Sub-shrublet up to 30 cm with a robust caudex, branched from the base. Stems glabrous or very shortly papillate, with two furrows. Lower leaves up to 30–35 mm long, fleshy, semi-terete, appressed to the stem or rarely recurved with tufts of hairs in their axils, without mucro or with a hardly noticeable mucro at the top. Bracts usually longer or equal to the flowers. Flowers solitary in the axil of the bract. Perianth segments greenish, 5, at fruiting stage with wings 2.0–2.5 × 2.5–3.5 mm, purple or lilac turning brownish. Anthers 5, ~1 mm long, ovate, apically without an appendage. Style short, 0.25 mm with 2–3 stigmas of the same length. Fruit whitish, depressed orbicular, ~1.5 mm in diameter.

Habitat. Rocky areas, semi-deserts and deserts at high elevations (3500–5200 m).

Phenology. Flowering: July–September; fruiting: September–October.

Distribution. See Fig. 53.

Figure 53. Distribution map of *Haloxylon thomsonii* (circles) and *Sympegma regelii* (stars).

Specimens examined. INDIA: Jammu & Kashmir (selected specimens): Shayuk valley, 24 Oct 1847, T.T. Thomson s.n. (K); Ladakh, Leh, Sep 1856, Schlagintweit 1587 (E); Ladakh, Saspol, 10500 ft a.s.l., 27 Aug 1931, W. Koelz 2706 (DD, E); Ladakh, 12000 ft a.s.l., Aug 1934, Kohli 4 (K); Ladakh, Lamayuru, 12000 ft a.s.l., 26 Jul 1937, C.C. Burt 52 (E); Leh, Phyang, 3500 m a.s.l., 14 Aug 1975, M.V. Klimeš 440 (PRA); Ladakh, Shyok, Hod-tong, 3280–3320 m a.s.l., 26 Sep 2004, L. Klimeš 5064 (PRA).

General distribution. North India and North Pakistan. Endemic to the Gilgit-Hunza-Indus river basins.

20. *Sympegma* Bunge, Bull. Acad. Imp. Sci. St.-Pétersbourg 25: 371 (1879)

Sympegma Bunge, Bull. Acad. Imp. Sci. St.-Pétersbourg 25: 371 (1879). **Type:** *S. regelii* Bunge.

Description. Subshrubs with several stems up to 40 cm tall; annual shoots glabrous or with tiny papillae (short simple hairs seen at higher magnification are present in the leaf axils). Leaves alternate, terete, green or glaucous, up to 2 cm long, mostly appressed to the

stem, broadened at base, but slightly constricted, straight or incurved above the base with a short persistent mucro. Inflorescences leafy; partial inflorescences pedicellate with opposite bracts enclosing (1–2)3–6 flowers. Perianth glabrous or papillate; perianth segments (4)5, 2.5–3.0 mm long, fused only basally, clearly three-nerved, margins glabrous or tiny papillate, with wing-like projections originating from the upper half of the segments at fruiting stage; wings yellowish, white or pink turning brown in mature fruits. Stamens 5, anthers ~1.5 mm long, with hardly noticeable appendage. Style very broad terminating with two stigmas. Seed with vertically orientated, spiral embryo. Perisperm absent.

Genus of 1–2 species. *Sympagma elegans* G.L.Chu (Zhu [Chu] and Sanderson 2017) described from Gansu Province (China) was not investigated by us. It reportedly differs from *S. regelii* by slender branches, shorter internodes and mostly solitary flowers (Zhu and Sanderson 2017).

1. *Sympagma regelii* Bunge, Bull. Acad. Imp. Sci. Saint-Pétersbourg 25: 371 (1879)

Lectotype (Grubov 1966): [CHINA, Xinjiang, Qitai County] basin of Bar-kul Lake towards Gucheng, 5 Sep 1875, P.A. Pyasetsky s.n. (LE).

Description. See genus description.

Habitat. Scree; 3500–4500 m a.s.l.

Phenology. Flowering: July–September; fruiting: August–October.

Distribution. See Fig. 53.

Specimens examined. CHINA: Xizang (new records): Ngari Prefecture: Rutog (Ritu) County, nr Bangong Lake, 4230 m a.s.l., 10 Jul 1974, Biological Institute Tibet Expedition Team 3461 (HNWP40809) & 4 Sep 1984, Qinghai-Tibet Team 1340 (HNWP146054); East bank of Bangong Lake, 4200 m a.s.l., 15 Aug 1987, B.S. Li & D. Zheng 11018 (PE01341763).

This is the first record of *S. regelii* in Xizang, and the records in the neighbouring areas of Jammu & Kashmir (India) are predicted. *Sympagma* is a common plant on the scree in North Pakistan and Xinjiang (Grubov 1966, Eberhardt et al. 2007, Hong and Blackmore 2015).

General distribution. W China, E Kazakhstan, Kyrgyzstan, Mongolia and Tajikistan.

Species of other genera excluded

Halocharis violacea Bunge, Anabas. Revis. 63 (1862) [Mém. Acad. Imp. Sci. St.-Pétersbourg, Sér. 7, 4(11)]

Notes. This species has been reported for Ladakh, India (Stewart 1916). No specimens were seen from our territory and the nearest records are from Quetta, Pakistan (Hedge 1997). This plant can be confused with *Halogenon glomeratus* (re-identifications in BSD) and both species are woolly at younger stages. Both genera can be

easily distinguished by the following leaf characteristics: the leaves of all *Halocharis* (tribe Caroxyleae) are covered with both short and long simple hairs, while those of *Halogeton* (tribe Salsoleae) are glabrous or covered with short papillae (long, clearly visible hairs are present only at the leaf base). The presence of two hair types is a distinct characteristic of *Halocharis* compared with many other Salsoloideae (Sukhorukov et al. 2016b).

Acknowledgements

We thank Eric H. Roalson, Pertti Uotila, Maria Flores Olvera, Gabriele Galasso, Georg and Sabine Miehe, Nicolas Fumeaux, Bohumil Mandak and Irina Belyaeva for discussion and suggestions regarding certain parts of the article. We cordially thank Ursine Hartmann who sent us the photographs of *Haloxylon thomsonii* (pictures taken in the 1990s by Hans Hartmann, who passed away in 2010), Dr. Basanmunkh Shukherdorj and Dr. Oyunsetseg Batlai for the image of *Halogeton glomeratus* and Dr. Prashant Awale for the images of *Suaeda olufsenii* and *Grubovia dasypylla*. The investigation of Alexander Sukhorukov and Maria Kushunina was carried out with support by a grant from the Russian Fund for Basic Research (taxonomic part: 18-04-00029-a). The revision of the herbaria in Moscow was supported by the scientific program AAAA-A16-116021660045-2 of the Department of Higher Plants, Moscow State University.
