Abstract
In the course of a taxonomic revision of *Pseudobombax* Dugand, one of us (JGCS) frequently has observed herbarium specimens of Bombacoideae that comprise a mixture of different Angiosperm families. In particular, *P. heteromorphum* (Kuntze) A.Robyns, a frequent name in checklists of the Bolivian flora, is based on type material of *Bombax heteromorphum* Kuntze that is clearly a mixture of *Pseudobombax* flowers and *Tabebuia* Gomes ex DC. (Bignoniaceae) leaves. We herein designate as the lectotype of *B. heteromorphum* the flowers of an herbarium sheet deposited in NY and as epitype a complete specimen (leaves, flowers, and fruit) in HUEFS. We consider *Bombax heteromorphum* to be a synonym of *P. longiflorum* (Mart.) A. Robyns, a species widespread in Neotropical seasonally dry forest of Bolivia, Brazil, Paraguay, and Peru. Furthermore, we describe a new species, *P. pulchellum* Carv.-Sobr., apparently endemic to seasonally dry tropical forest (SDTF) in Bolivia (Chiquitano dry forest), based on specimens commonly but incorrectly identified as *P. heteromorphum*. We also comment on the morphology, distribution, and conservation status of this new species.

Resumen
En el curso de una revisión taxonómica de *Pseudobombax* Dugand, uno de nosotros (JGCS) con frecuencia ha observado especímenes de herbario de Bombacoideae que comprenden una mezcla de diferentes familias de angiospermas. En particular, *P. heteromorphum* (Kuntze) A.Robyns, un nombre frecuente en las listas de la flora boliviana, se basa en el material tipo de *Bombax heteromorphum* Kuntze que es claramente una mezcla de flores de *Pseudobombax* y hojas de *Tabebuia* Gomes ex DC. (Bignoniaceae). Aquí se designa como el lectotipo de *B. heteromorphum* las flores de uno de los especímenes de herbario de NY y como epítipo uno...
espécimen completo (hojas, flores y frutos) de el herbario HUEFS. Consideramos Bombax heteromorphum como sinónimo de P. longiflorum (Mart.) A.Robyns, una especie ampliamente distribuida en los bosques neotropicales estacionalmente seco de Bolivia, Brasil, Paraguay y Perú. Por otra parte, se describe una especie nueva, P. pulchellum Carv.-Sobr., aparentemente endémica de los Bosques secos Chiquitanos en Bolivia, con base en colecciones comúnmente, pero incorrectamente identificado, como P. heteromorphum, con comentarios sobre su morfología, distribución y estado de conservación.

Introduction
In his revision of Bombax L. s.l., Robyns (1963) transferred B. heteromorphum Kuntze to Pseudobombax Dugand and considered P. heteromorphum (Kuntze) A.Robyns to be endemic to Bolivia. Based solely on the holotype of B. heteromorphum (Kuntze s.n., Fig. 1), Robyns described P. heteromorphum as having long petiolules and scarcely expanded petiole apices. In his key to the species of Pseudobombax, he used these two characters to separate this species from morphologically closely related congeners. According to Robyns’s description, P. heteromorphum also has grooved (canaliculate) petiolules, which if true would represent a unique character in the genus Pseudobombax.

In the course of a taxonomic revision of Pseudobombax (Carvalho-Sobrinho, in prep.), mixed collections of Bombacoideae, including type specimens based on mixtures, often have been observed. This is especially common for collections from seasonally dry Neotropical forest habitats where species often are leafless during the flowering period. In the present case, a careful examination of the morphology of the leaves and flowers of the holotype of Bombax heteromorphum revealed that the specimen is a mixture of reproductive and vegetative elements from two different Angiosperm families. Robyns (1963) failed to note that his type specimen has leaflets that are articulated with the petiole, a character state unknown in Pseudobombax; the genus is separated from all other Bombacoideae by the synapomorphy of non-articulated leaflets, which lack an abscission zone between the apex of the petiole and the base of the petiolules (Robyns 1963, Carvalho-Sobrinho and Queiroz 2011).

The holotype of Bombax heteromorphum (NY) and an image of an isotype (B as F negative 9535; Field Museum 2012) show floral material matching that of Pseudobombax longiflorum (Mart.) A.Robyns, including an androecium with a glabrous, relatively long staminal tube, filaments freely originating from the apex of the tube (i.e., without phalanges), and typical hippocrepiform anthers. However, the vegetative material of these two type specimens matches the leaves of Tabebuia aurea (Silva Manso) Benth. & Hook. f. ex S. Moore (Bignoniaceae), with suberous branches, opposite leaves (inferred from leaf scars), longer and grooved petiolules, leaflets with a clear abscission zone, and a clearly different venation pattern (Fig. 1). Pseudobombax longiflorum, a

species widespread in Neotropical seasonally dry forest of Bolivia, Brazil, Paraguay, and Peru, and _T. aurea_ are sympatric in the Bolivian Chiquitano dry forest and the latter species has been collected several times in the type locality of _B. heteromorphum_ (municipality of Velasco, Santa Cruz, Bolivia) according to Tropicos (2012) and specimen labels from herbaria (F, US, and WIS).

**Lectotypification of Bombax heteromorphum**

Having demonstrated above that the holotype of _Bombax heteromorphum_ represents a mixture of leaves belonging to _Tabebuia aurea_ and detached flowers belonging to a species of _Pseudobombax_ it becomes necessary to select a lectotype from these two elements in order to fix the application of the name (McNeill et al. 2012, Art. 9.14). We choose to lectotypify the name on the flowers only because the name _B. heteromorphum_ always has been associated with Malvaceae.

**A new species of Pseudobombax long confused with P. heteromorphum**

Robyns (1963) and subsequent authors (Killeen et al. 1993, Jardim et al. 2003) assigned specimens of a distinctive Bolivian species of _Pseudobombax_ to _P. heteromorphum_ in error. These collections in fact represent a new species, which we describe here.

Figs 2, 3

**Diagnosis.** Similar to _Pseudobombax longiflorum_ (Mart.) A. Robyns by its long petiolules, obovate to suborbicular leaflets, and maculate seeds, but differing by the smaller leaves, flowers and fruits, slender branches, petioles 4 times the length of the petiolules
Reinterpretation of the nomenclatural type of *Pseudobombax heteromorphum*...

(vs. a petiole/petiolule ratio of 6–12 in *P. longiflorum*), and fruits acuminate for the distal 20% of their length (vs. 3%–5% in *P. longiflorum*).

**Type.** BOLIVIA. Santa Cruz: 42 km E of Curuyuqui, 18°45′56″S, 62°13′59″W, 350 m, 25 October 1991 (lf, fr), A. Gentry, R. Foster & M. Peña 75227 (holotype: MO!; isotypes: F!, LPB!, USZ!, WIS!).

**Description.** Treelets 3–8 m, deciduous; branches glabrous, relatively slender, often covered with pale wax; brachyblasts absent. Stipules not seen. Leaves palmpately compound, clustered at apex of the branches; petioles (17–)34–87 mm long, flattened, slender, glabrous, usually glaucous with pale wax at the ends, bases slightly thickened, apices slightly thickened to 3–4 mm diam.; petiolules 14–22 mm long; leaflets (4) 5 (7), chartaceous, proximal leaflets 17–38 × 9–30 mm, distal leaflets 45–57(–75) × 29–51 mm, obovate, broadly elliptic to suborbicular, apices retuse, rarely acuminate, bases obtuse, rounded, truncate to slightly cordate, margins entire, glabrous on both surfaces, except for sparse, peltate microtrichomes, abaxial surface dull-brown in dried state, midrib prominent abaxially, 8–12 secondary veins inconspicuous, intersecondary veins present, tertiary veins reticulate. Complete inflorescences not seen; pedicels 19 mm long (–26 mm when in fruit). Flowers c. 65 mm long; receptacle with single whorl of c. 5 glands; calyces 8–9 × 11–15 mm, cupular to campanulate, truncate, outwardly glabrous except for peltate microtrichomes, internally sericeous; petals (50–)61–70 × 6–8 mm, linear to lanceolate, apex acute, dark-brown externally, covered with tufted, rigid hairs, inwardly pilose to glabrescent towards the base, covered mainly by verrucose microtrichomes; stamens c. 150–200, staminal tube 9–10 × 4 mm, pubescent, phalanges absent, filaments free for 40–58 mm, anthers hippocrepiform c. 2 mm long; ovary 5 × 2 mm, oblong-obovoid, glabrous except for peltate microtrichomes, style c. 70 mm long, glabrous, stigma inconspicuously 5-lobed. Capsules c. 90 mm long, woody, oblong-obovoid, conspicuously acuminate for distal 15 mm or so, valves coriaceous, glabrous, kapok abundant, golden brown. Seeds c. 5 mm diam., subglobose to pyriform, maculate, glabrous.

**Distribution.** *Pseudobombax pulchellum* is known from only four sites in the Department of Santa Cruz, Bolivia, and appears to be endemic to Chiquitano dry forest at elevations of 230 to 520 m.

**Phenology.** Flowers of this new species are known from a single collection made in June; fruiting material was collected in October.

**Etymology.** The specific epithet refers to the small, delicate leaflets and long, slender petiolules of this species, diagnostic even in sterile specimens. The epithet also honors the Brazilian botanist Aline Costa da Mota for her important insights and collaboration on the systematics of Bombacoideae.

**Conservation status.** Although *Pseudobombax pulchellum* occurs in the Kaa-Iya del Gran Chaco National Park, it must be considered Near Threatened because it is known from only four sites and “there are plausible events that may cause the species to decline, but these are unlikely to make the species Extinct or Critically Endangered in a short time” (IUCN 2010). Extensive fieldwork in other areas of dry forests in Bolivia is necessary to properly survey and to assess the status of this species.
Figure 2. Photograph of an isotype of *Pseudobombax pulchellum* Carv.-Sobr. *(Gentry et al. 75227, F 2111431).*
Specimens examined. BOLIVIA. Santa Cruz: Chiquitos, 19–23 Dec 1993 (fr), G. Navarro Sanchez 2192 (LPB!); Cordillera, 09 January 1993 (lf), G. Navarro Sanchez 1713 (MO!, USZ!); ibidem, 18°29’20”S, 61°07’06”W, 230 m, 17 June 1998 (fl), Alfredo F. Fuentes & G. Navarro Sanchez 2436 (MO!); Ñuflo de Chavez, 17°05’00”S, 61°47’00”W, 400 m, 24 October 1995 (lf), Alfredo F. Fuentes 1132 (LPB!, USZ,WIS!).

Discussion. *Pseudobombax pulchellum* is a remarkable species by its diminutive aspect, especially the relatively small, retuse, obovate to suborbicular leaflets, and the flowers; the petiolules are markedly long in relation to the petiole, and fruits are conspicuously acuminate. It seems to be closely related to *P. longiflorum* (Mart.) A. Robyns, a sympatric congener in Bolivian Chiquitano dry forest. The two are similar because of their glabrous aspect, long petiolules, leaflets with retuse apices, truncate to cordate bases, and maculate seeds.
The new species is also similar to *Pseudobombax croizatii* A.Robyns and *P. minimum* Carv.-Sobr. & L.P. Queiroz; both of these species share small flowers (60–65 mm long), glabrous staminal tubes, androecia with relatively few stamens (c. 150–200), and glabrous fruits. The following key can be used to separate these four species of *Pseudobombax.*

1 Petiolules 14–75 mm long. Petals externally blackish, staminal tube lacking phalanges (filaments freely originating from the apex of the tube). Seeds bicolored, maculate.................................................................2

– Petiolules to 5 mm long. Petals externally cream-colored, staminal tube originating phalanges 3–5 mm long. Seeds uniformly colored........................................3

2 Petioles 4 times the length of the petiolules. Flowers c. 65 mm long, calyx 8–9 mm long, staminal tube c. 10 mm long. Capsules c. 90 mm long, acuminate for the distal 20% of their length ............... *P. pulchellum* (Bolivia)

– Petioles 6–12 times the length of the petiolules. Flowers 15–22 mm long, calyx 15–25 mm long, staminal tube 35–60 mm long. Capsules 14–24 mm long, acuminate for the distal 3%–5% of their length.............................

........................................*P. longiflorum* (Bolivia, Brazil, Paraguay, Peru)

3 Leaflets 7–9, obovate, cuneate, margins revolute. Flowers to 60 mm long, staminal tube glabrous. Capsules 55 mm long, not acuminate.........................................................*P. minimum* (Central Brazil)

– Leaflets 5, elliptic to broad-elliptic, acute, margins plane. Flowers 85–100 mm long, staminal tube with bands of simple trichomes. Capsules c. 70 mm long, acuminate ...................... *P. croizatii* (Colombia, Venezuela)

**Acknowledgements**

Thanks are due Hibert Huaylla for photographs of Bombacoideae specimens from Bolivia; the staff and curators of F (especially Nancy Hensold and Robin Foster), LPB, MO, NY, and WIS for scanned images; the reviewers and the subject editor for their suggestions to the manuscript; the Fundação de Amparo à Pesquisa do Estado da Bahia (process APP0006/2011) and the Conselho Nacional de Desenvolvimento Científico e Tecnológico–CNPq (processes 300811/2010-1 and 563546/2010-7-REFLORA) for financial support. This paper is part of the PhD thesis of JGCS prepared in the Programa de Pós-Graduação em Botânica (PPGBot-UEFS) and supported by a grant from the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior–CAPES.
